EUROPEAN STANDARD

NORME EUROPÉENNE

EUROPÄISCHE NORM

EN 1992-1-1

December 2004

English version

Eurocode 2: Design of concrete structures - Part 1-1: General rules and rules for buildings

Eurocode 2: Calcul des structures en béton - Partie 1-1 : Règles générales et règles pour les bâtiments

Eurocode 2: Bemessung und konstruktion von Stahlbeton- und Spannbetontragwerken - Teil 1-1: Allgemeine Bemessungsregeln und Regeln für den Hochbau

This European Standard was approved by CEN on 16 April 2004.

CEN members are bound to comply with the CEN/CENELEC Internal Regulations which stipulate the conditions for giving this European Standard the status of a national standard without any alteration. Up-to-date lists and bibliographical references concerning such national standards may be obtained on application to the Central Secretariat or to any CEN member.

This European Standard exists in three official versions (English, French, German). A version in any other language made by translation under the responsibility of a CEN member into its own language and notified to the Central Secretariat has the same status as the official versions.

CEN members are the national standards bodies of Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, Switzerland and United Kingdom.

Contents List

Foreword

This European Standard EN 1992, Eurocode 2: Design of concrete structures: General rules and rules for buildings, has been prepared by Technical Committee CEN/TC250 « Structural Eurocodes », the Secretariat of which is held by BSI. CEN/TC250 is responsible for all Structural Eurocodes.

This European Standard shall be given the status of a National Standard, either by publication of an identical text or by endorsement, at the latest by June 2005, and conflicting National Standards shall be withdrawn at latest by March 2010.

This Eurocode supersedes ENV 1992-1-1, 1992-1-3, 1992-1-4, 1992-1-5, 1992-1-6 and 1992-3.

According to the CEN-CENELEC Internal Regulations, the National Standard Organisations of the following countries are bound to implement these European Standard: Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary,

Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, Switzerland and United Kingdom.

Background to the Eurocode programme

In 1975, the Commission of the European Community decided on an action programme in the field of construction, based on article 95 of the Treaty. The objective of the programme was the elimination of technical obstacles to trade and the harmonisation of technical specifications.

Within this action programme, the Commission took the initiative to establish a set of harmonised technical rules for the design of construction works which, in a first stage, would serve as an alternative to the national rules in force in the Member States and, ultimately, would replace them.

For fifteen years, the Commission, with the help of a Steering Committee with Representatives of Member States, conducted the development of the Eurocodes programme, which led to the first generation of European codes in the 1980s.

In 1989, the Commission and the Member States of the EU and EFTA decided, on the basis of an agreement[1] between the Commission and CEN, to transfer the preparation and the publication of the Eurocodes to CEN through a series of Mandates, in order to provide them with a future status of European Standard (EN). This links *de facto* the Eurocodes with the provisions of all the Council's Directives and/or Commission's Decisions dealing with European standards (*e.g.* the Council Directive 89/106/EEC on construction products - CPD - and Council Directives 93/37/EEC, 92/50/EEC and 89/440/EEC on public works and services and equivalent EFTA Directives initiated in pursuit of setting up the internal market).

The Structural Eurocode programme comprises the following standards generally consisting of a number of Parts:

EN 1990	Eurocode 0:	Basis of Structural Design
EN 1991	Eurocode 1:	Actions on structures
EN 1992	Eurocode 2:	Design of concrete structures
EN 1993	Eurocode 3:	Design of steel structures
EN 1994	Eurocode 4:	Design of composite steel and concrete structures
EN 1995	Eurocode 5:	Design of timber structures
EN 1996	Eurocode 6:	Design of masonry structures
EN 1997	Eurocode 7:	Geotechnical design
EN 1998	Eurocode 8:	Design of structures for earthquake resistance
EN 1999	Eurocode 9:	Design of aluminium structures

Eurocode standards recognise the responsibility of regulatory authorities in each Member State and have safeguarded their right to determine values related to regulatory safety matters at national level where these continue to vary from State to State.

Status and field of application of eurocodes

The Member States of the EU and EFTA recognise that Eurocodes serve as reference documents for the following purposes :

– as a means to prove compliance of building and civil engineering works with the essential

---

[1] Agreement between the Commission of the European Communities and the European Committee for Standardisation (CEN) concerning the work on EUROCODES for the design of building and civil engineering works (BC/CEN/03/89).

requirements of Council Directive 89/106/EEC, particularly Essential Requirement N°1 – Mechanical resistance and stability – and Essential Requirement N°2 – Safety in case of fire;

– as a basis for specifying contracts for construction works and related engineering services;

– as a framework for drawing up harmonised technical specifications for construction products (ENs and ETAs)

The Eurocodes, as far as they concern the construction works themselves, have a direct relationship with the Interpretative Documents[2] referred to in Article 12 of the CPD, although they are of a different nature from harmonised product standards[3]. Therefore, technical aspects arising from the Eurocodes work need to be adequately considered by CEN Technical Committees and/or EOTA Working Groups working on product standards with a view to achieving full compatibility of these technical specifications with the Eurocodes.

The Eurocode standards provide common structural design rules for everyday use for the design of whole structures and component products of both a traditional and an innovative nature. Unusual forms of construction or design conditions are not specifically covered and additional expert consideration will be required by the designer in such cases.

National Standards implementing Eurocodes

The National Standards implementing Eurocodes will comprise the full text of the Eurocode (including any annexes), as published by CEN, which may be preceded by a National title page and National foreword, and may be followed by a National annex.

The National annex may only contain information on those parameters which are left open in the Eurocode for national choice, known as Nationally Determined Parameters, to be used for the design of buildings and civil engineering works to be constructed in the country concerned, *i.e.* :
– values and/or classes where alternatives are given in the Eurocode,
– values to be used where a symbol only is given in the Eurocode,
– country specific data (geographical, climatic, etc.), *e.g.* snow map,
– the procedure to be used where alternative procedures are given in the Eurocode.
It may contain
– decisions on the application of informative annexes,
– references to non-contradictory complementary information to assist the user to apply the Eurocode.

Links between Eurocodes and harmonised technical specifications (ENs and ETAs) for products

There is a need for consistency between the harmonised technical specifications for

---

[2] According to Art. 3.3 of the CPD, the essential requirements (ERs) shall be given concrete form in interpretative documents for the creation of the necessary links between the essential requirements and the mandates for harmonised ENs and ETAGs/ETAs.

[3] According to Art. 12 of the CPD the interpretative documents shall :
a) give concrete form to the essential requirements by harmonising the terminology and the technical bases and indicating classes or levels for each requirement where necessary ;
b)   indicate methods of correlating these classes or levels of requirement with the technical specifications, *e.g.* methods of calculation and of proof, technical rules for project design, etc. ;
c) serve as a reference for the establishment of harmonised standards and guidelines for European technical approvals.

The Eurocodes, *de facto*, play a similar role in the field of the ER 1 and a part of ER 2.

construction products and the technical rules for works[4]. Furthermore, all the information accompanying the CE Marking of the construction products which refer to Eurocodes should clearly mention which Nationally Determined Parameters have been taken into account.

Additional information specific to EN 1992-1-1

EN 1992-1-1 describes the principles and requirements for safety, serviceability and durability of concrete structures, together with specific provisions for buildings. It is based on the limit state concept used in conjunction with a partial factor method.

For the design of new structures, EN 1992-1-1 is intended to be used, for direct application, together with other parts of EN 1992, Eurocodes EN 1990,1991, 1997 and 1998.

EN 1992-1-1 also serves as a reference document for other CEN TCs concerning structural matters.

EN 1992-1-1 is intended for use by:
– committees drafting other standards for structural design and related product, testing and execution standards;
– clients (e.g. for the formulation of their specific requirements on reliability levels and durability);
– designers and constructors ;
– relevant authorities.

Numerical values for partial factors and other reliability parameters are recommended as basic values that provide an acceptable level of reliability. They have been selected assuming that an appropriate level of workmanship and of quality management applies. When EN 1992-1-1 is used as a base document by other CEN/TCs the same values need to be taken.

National annex for EN 1992-1-1

This standard gives values with notes indicating where national choices may have to be made. Therefore the National Standard implementing EN 1992-1-1 should have a National annex containing all Nationally Determined Parameters to be used for the design of buildings and civil engineering works to be constructed in the relevant country.

National choice is allowed in EN 1992-1-1 through the following clauses:

SECTION 1 GENERAL

1.1   Scope

1.1.1 Scope of Eurocode 2

(1)P Eurocode 2 applies to the design of buildings and civil engineering works in plain, reinforced and prestressed concrete. It complies with the principles and requirements for the safety and serviceability of structures, the basis of their design and verification that are given in EN 1990: Basis of structural design.

(2)P Eurocode 2 is only concerned with the requirements for resistance, serviceability, durability and fire resistance of concrete structures. Other requirements, e.g. concerning thermal or sound insulation, are not considered.

(3)P Eurocode 2 is intended to be used in conjunction with:

EN 1990:   Basis of structural design
EN 1991:   Actions on structures
hEN's: Construction products relevant for concrete structures
ENV 13670:   Execution of concrete structures
EN 1997:   Geotechnical design
EN 1998:   Design of structures for earthquake resistance, when concrete structures are built in
             seismic regions.

(4)P Eurocode 2 is subdivided into the following parts:

Part 1.1:   General rules and rules for buildings
Part 1.2:   Structural fire design
Part 2:   Reinforced and prestressed concrete bridges
Part 3:   Liquid retaining and containing structures

1.1.2 Scope of Part 1-1 of Eurocode 2

(1)P Part 1-1 of Eurocode 2 gives a general basis for the design of structures in plain, reinforced and prestressed concrete made with normal and light weight aggregates together with specific rules for buildings.

(2)P The following subjects are dealt with in Part 1-1.

Section 1:   General
Section 2:   Basis of design
Section 3:   Materials
Section 4:   Durability and cover to reinforcement
Section 5:   Structural analysis
Section 6:   Ultimate limit states
Section 7:   Serviceability limit states
Section 8:   Detailing of reinforcement and prestressing tendons - General
Section 9:   Detailing of members and particular rules

Section 10:   Additional rules for precast concrete elements and structures
Section 11:   Lightweight aggregate concrete structures
Section 12:   Plain and lightly reinforced concrete structures

(3)P Sections 1 and 2 provide additional clauses to those given in EN 1990 "Basis of structural design".

(4)P This Part 1-1 does not cover:
- the use of plain reinforcement
- resistance to fire;
- particular aspects of special types of building (such as tall buildings);
- particular aspects of special types of civil engineering works (such as viaducts, bridges, dams, pressure vessels, offshore platforms or liquid-retaining structures);
- no-fines concrete and aerated concrete components, and those made with heavy aggregate or containing structural steel sections (see Eurocode 4 for composite steel-concrete structures).

1.2   Normative references

(1)P The following normative documents contain provisions which, through references in this text, constitutive provisions of this European standard. For dated references, subsequent amendments to or revisions of any of these publications do not apply. However, parties to agreements based on this European standard are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. For undated references the latest edition of the normative document referred to applies.

1.2.1 General reference standards

EN 1990:   Basis of structural design
EN 1991-1-5:   Actions on structures: Thermal actions
EN 1991-1-6:   Actions on structures: Actions during execution

1.2.2 Other reference standards

EN1997:   Geotechnical design
EN 197-1:   Cement: Composition, specification and conformity criteria for common cements
EN 206-1:   Concrete: Specification, performance, production and conformity
EN 12390:   Testing hardened concrete
EN 10080:   Steel for the reinforcement of concrete
EN 10138:   Prestressing steels
EN ISO 17760:   Permitted welding process for reinforcement
ENV 13670:   Execution of concrete structures
EN 13791:   Testing concrete
EN ISO 15630   Steel for the reinforcement and prestressing of concrete: Test methods

1.3   Assumptions

(1)P In addition to the general assumptions of EN 1990 the following assumptions apply:
- Structures are designed by appropriately qualified and experienced personnel.

- Adequate supervision and quality control is provided in factories, in plants, and on site.
- Construction is carried out by personnel having the appropriate skill and experience.
- The construction materials and products are used as specified in this Eurocode or in the relevant material or product specifications.
- The structure will be adequately maintained.
- The structure will be used in accordance with the design brief.
- The requirements for execution and workmanship given in ENV 13670 are complied with.

1.4   Distinction between principles and application rules

(1)P The rules given in EN 1990 apply.

1.5   Definitions

1.5.1 General

(1)P The terms and definitions given in EN 1990 apply.

1.5.2 Additional terms and definitions used in this Standard

1.5.2.1 Precast structures. Precast structures are characterised by structural elements manufactured elsewhere than in the final position in the structure. In the structure, elements are connected to ensure the required structural integrity.

1.5.2.2 Plain or lightly reinforced concrete members. Structural concrete members having no reinforcement (plain concrete) or less reinforcement than the minimum amounts defined in Section 9.

1.5.2.3 Unbonded and external tendons. Unbonded tendons for post-tensioned members having ducts which are permanently ungrouted, and tendons external to the concrete cross-section (which may be encased in concrete after stressing, or have a protective membrane).

1.5.2.4 Prestress. The process of prestressing consists in applying forces to the concrete structure by stressing tendons relative to the concrete member. "Prestress" is used globally to name all the permanent effects of the prestressing process, which comprise internal forces in the sections and deformations of the structure. Other means of prestressing are not considered in this standard.

1.6   Symbols

For the purposes of this standard, the following symbols apply.

> **Note:** The notation used is based on ISO 3898:1987

Latin upper case letters

A	Accidental action
A	Cross sectional area
A_c	Cross sectional area of concrete
A_p	Area of a prestressing tendon or tendons

A_s Cross sectional area of reinforcement

$A_{s,min}$ minimum cross sectional area of reinforcement

A_{sw} Cross sectional area of shear reinforcement

D Diameter of mandrel

D_{Ed} Fatigue damage factor

E Effect of action

E_c, $E_{c(28)}$ Tangent modulus of elasticity of normal weight concrete at a stress of $\sigma_c = 0$ and at 28 days

$E_{c,eff}$ Effective modulus of elasticity of concrete

E_{cd} Design value of modulus of elasticity of concrete

E_{cm} Secant modulus of elasticity of concrete

$E_c(t)$ Tangent modulus of elasticity of normal weight concrete at a stress of $\sigma_c = 0$ and at time t

E_p Design value of modulus of elasticity of prestressing steel

E_s Design value of modulus of elasticity of reinforcing steel

EI Bending stiffness

EQU   Static equilibrium

F Action

F_d Design value of an action

F_k Characteristic value of an action

G_k Characteristic permanent action

I Second moment of area of concrete section

L Length

M Bending moment

M_{Ed} Design value of the applied internal bending moment

N Axial force

N_{Ed} Design value of the applied axial force (tension or compression)

P Prestressing force

P_0 Initial force at the active end of the tendon immediately after stressing

Q_k Characteristic variable action

Q_{fat} Characteristic fatigue load

R Resistance

S Internal forces and moments

S First moment of area

SLS   Serviceability limit state

T Torsional moment

T_{Ed} Design value of the applied torsional moment

ULS   Ultimate limit state

V Shear force

V_{Ed} Design value of the applied shear force

Latin lower case letters

a Distance

a Geometrical data

Δa Deviation for geometrical data

b Overall width of a cross-section, or actual flange width in a T or L beam

b_w Width of the web on T, I or L beams

d Diameter ; Depth

d Effective depth of a cross-section

d_g Largest nominal maximum aggregate size

e Eccentricity

f_c Compressive strength of concrete

f_{cd} Design value of concrete compressive strength

f_{ck} Characteristic compressive cylinder strength of concrete at 28 days

f_{cm} Mean value of concrete cylinder compressive strength

f_{ctk} Characteristic axial tensile strength of concrete

f_{ctm} Mean value of axial tensile strength of concrete

f_p Tensile strength of prestressing steel

f_{pk} Characteristic tensile strength of prestressing steel

$f_{p0,1}$ 0,1% proof-stress of prestressing steel

$f_{p0,1k}$ Characteristic 0,1% proof-stress of prestressing steel

$f_{0,2k}$ Characteristic 0,2% proof-stress of reinforcement

f_t Tensile strength of reinforcement

f_{tk} Characteristic tensile strength of reinforcement

f_y Yield strength of reinforcement

f_{yd} Design yield strength of reinforcement

f_{yk} Characteristic yield strength of reinforcement

f_{ywd} Design yield of shear reinforcement

h Height

h Overall depth of a cross-section

i Radius of gyration

k Coefficient ; Factor

l (or I or L) Length; Span

m Mass

r Radius

$1/r$ Curvature at a particular section

t Thickness

t Time being considered

t_0 The age of concrete at the time of loading

u Perimeter of concrete cross-section, having area A_c

u,v,w Components of the displacement of a point

x Neutral axis depth

x,y,z Coordinates

z Lever arm of internal forces

Greek lower case letters

α Angle ; ratio

β Angle ; ratio; coefficient

γ Partial factor

γ_A Partial factor for accidental actions A

γ_C Partial factor for concrete

γ_F Partial factor for actions, F

$\gamma_{F,fat}$ Partial factor for fatigue actions

$\gamma_{C,fat}$ Partial factor for fatigue of concrete

γ_G Partial factor for permanent actions, G

γ_M Partial factor for a material property, taking account of uncertainties in the material property itself, in geometric deviation and in the design model used

γ_P Partial factor for actions associated with prestressing, P

γ_Q Partial factor for variable actions, Q

γ_S Partial factor for reinforcing or prestressing steel

$\gamma_{S,fat}$ Partial factor for reinforcing or prestressing steel under fatigue loading

γ_f Partial factor for actions without taking account of model uncertainties

γ_g Partial factor for permanent actions without taking account of model uncertainties

γ_m Partial factors for a material property, taking account only of uncertainties in the material property

δ Increment/redistribution ratio

ζ Reduction factor/distribution coefficient

ε_c Compressive strain in the concrete

ε_{c1} Compressive strain in the concrete at the peak stress f_c

ε_{cu} Ultimate compressive strain in the concrete

ε_u Strain of reinforcement or prestressing steel at maximum load

ε_{uk} Characteristic strain of reinforcement or prestressing steel at maximum load

θ Angle

λ Slenderness ratio

μ Coefficient of friction between the tendons and their ducts

ν Poisson's ratio

ν Strength reduction factor for concrete cracked in shear

ξ Ratio of bond strength of prestressing and reinforcing steel

ρ Oven-dry density of concrete in kg/m^3

ρ_{1000} Value of relaxation loss (in %), at 1000 hours after tensioning and at a mean temperature of 20°C

ρ_l Reinforcement ratio for longitudinal reinforcement

ρ_w Reinforcement ratio for shear reinforcement

σ_c Compressive stress in the concrete

σ_{cp} Compressive stress in the concrete from axial load or prestressing

σ_{cu} Compressive stress in the concrete at the ultimate compressive strain ε_{cu}

τ Torsional shear stress

ϕ Diameter of a reinforcing bar or of a prestressing duct

ϕ_n Equivalent diameter of a bundle of reinforcing bars

$\varphi(t,t_0)$ Creep coefficient, defining creep between times t and t_0, related to elastic deformation at 28 days

$\varphi(\infty,t_0)$ Final value of creep coefficient

ψ Factors defining representative values of variable actions

     ψ_0 for combination values

     ψ_1 for frequent values

     ψ_2 for quasi-permanent values

SECTION 2 BASIS OF DESIGN

2.1   Requirements

2.1.1 Basic requirements

(1)P The design of concrete structures shall be in accordance with the general rules given in EN 1990.

(2)P The supplementary provisions for concrete structures given in this section shall also be applied.

(3) The basic requirements of EN 1990 Section 2 are deemed to be satisfied for concrete structures when the following are applied together:
   - limit state design in conjunction with the partial factor method in accordance with EN 1990,
   - actions in accordance with EN 1991,
   - combination of actions in accordance with EN 1990 and
   - resistances, durability and serviceability in accordance with this Standard.

   Note: Requirements for fire resistance (see EN 1990 Section 5 and EN 1992-1-2) may dictate a greater size of member than that required for structural resistance at normal temperature.

2.1.2 Reliability management

(1) The rules for reliability management are given in EN 1990 Section 2.

(2) A design using the partial factors given in this Eurocode (see 2.4) and the partial factors given in the EN 1990 annexes is considered to lead to a structure associated with reliability Class RC2.

   Note: For further information see EN 1990 Annexes B and C.

2.1.3 Design working life, durability and quality management

(1) The rules for design working life, durability and quality management are given in EN 1990 Section 2.

2.2   Principles of limit state design

(1) The rules for limit state design are given in EN 1990 Section 3.

2.3   Basic variables

2.3.1 Actions and environmental influences

2.3.1.1 General

(1) Actions to be used in design may be obtained from the relevant parts of EN 1991.

   Note 1: The relevant parts of EN1991 for use in design include:

20

EN 1991-1.1   Densities, self-weight and imposed loads
EN 1991-1. 2   Fire actions
EN 1991-1.3   Snow loads
EN 1991-1.4   Wind loads
EN 1991-1.5   Thermal actions
EN 1991-1.6   Actions during execution
EN 1991-1.7   Accidental actions due to impact and explosions
EN 1991-2 Traffic loads on bridges
EN 1991-3 Actions induced by cranes and other machinery
EN 1991-4 Actions in silos and tanks

Note 2: Actions specific to this Standard are given in the relevant sections.

Note 3: Actions from earth and water pressure may be obtained from EN 1997.

Note 4: When differential movements are taken into account, appropriate estimate values of predicted movements may be used.

Note 5: Other actions, when relevant, may be defined in the design specification for a particular project.

2.3.1.2 Thermal effects

(1) Thermal effects should be taken into account when checking serviceability limit states.

(2) Thermal effects should be considered for ultimate limit states only where they are significant (e.g. fatigue conditions, in the verification of stability where second order effects are of importance, etc). In other cases they need not be considered, provided that the ductility and rotation capacity of the elements are sufficient.

 (3) Where thermal effects are taken into account they should be considered as variable actions and applied with a partial factor and ψ factor.

Note: The ψ factor is defined in the relevant annex of EN 1990 and EN 1991-1-5.

2.3.1.3 Differential settlements/movements

(1) Differential settlements/movements of the structure due to soil subsidence should be classified as a permanent action, G_{set} which is introduced as such in combinations of actions. In general, G_{set} is represented by a set of values corresponding to differences (compared to a reference level) of settlements/movements between individual foundations or part of foundations, $d_{set,i}$ (i denotes the number of the individual foundation or part of foundation).

Note: Where differential settlements are taken into account, appropriate estimate values of predicted settlements may be used.

(2) The effects of differential settlements should generally be taken into account for the verification for serviceability limit states.

(3) For ultimate limit states they should be considered only where they are significant (e.g. fatigue conditions, in the verification of stability where second order effects are of importance, etc). In other cases for ultimate limit states they need not be considered, provided that the ductility and rotation capacity of the elements are sufficient.

(4) Where differential settlements are taken into account a partial safety factor for settlement effects should be applied.

Note: The value of the partial safety factor for settlement effects is defined in the relevant annex of EN1990.

2.3.1.4 Prestress

(1)P The prestress considered in this Eurocode is applied by tendons made of high-strength steel (wires, strands or bars).

(2) Tendons may be embedded in the concrete. They may be pre-tensioned and bonded or post-tensioned and bonded or unbonded.

(3) Tendons may also be external to the structure with points of contact occurring at deviators and anchorages.

(4) Provisions concerning prestress are found in 5.10.

2.3.2 Material and product properties

2.3.2.1 General

(1) The rules for material and product properties are given in EN 1990 Section 4.

(2) Provisions for concrete, reinforcement and prestressing steel are given in Section 3 or the relevant Product Standard.

2.3.2.2 Shrinkage and creep

(1) Shrinkage and creep are time-dependent properties of concrete. Their effects should generally be taken into account for the verification of serviceability limit states.

(2) The effects of shrinkage and creep should be considered at ultimate limit states only where their effects are significant, for example in the verification of ultimate limit states of stability where second order effects are of importance. In other cases these effects need not be considered for ultimate limit states, provided that ductility and rotation capacity of the elements are sufficient.

(3) When creep is taken into account its design effects should be evaluated under the quasi-permanent combination of actions irrespective of the design situation considered i.e. persistent, transient or accidental.

Note: In most cases the effects of creep may be evaluated under permanent loads and the mean value of prestress.

2.3.3 Deformations of concrete

(1)P The consequences of deformation due to temperature, creep and shrinkage shall be considered in design.

(2) The influence of these effects is normally accommodated by complying with the application rules of this Standard. Consideration should also be given to:
- minimising deformation and cracking due to early-age movement, creep and shrinkage through the composition of the concrete mix;
- minimising restraints to deformation by the provision of bearings or joints;

- if restraints are present, ensuring that their influence is taken into account in design.

(3) In building structures, temperature and shrinkage effects may be omitted in global analysis provided joints are incorporated at every distance d_{joint} to accommodate resulting deformations.

> **Note:** The value of d_{joint} is subject to a National Annex. The recommended value is 30 m. For precast concrete structures the value may be larger than that for cast in-situ structures, since part of the creep and shrinkage takes place before erection.

2.3.4 Geometric data

2.3.4.1 General

(1) The rules for geometric data are given in EN 1990 Section 4.

2.3.4.2 Supplementary requirements for cast in place piles

(1)P Uncertainties related to the cross-section of cast in place piles and concreting procedures shall be allowed for in design.

(2) In the absence of other provisions the diameter used in design calculations, of cast in place piles without permanent casing should be taken as:
- if d_{nom} < 400 mm $d = d_{nom}$ - 20 mm
- if 400 $\leq d_{nom} \leq$ 1000 mm $d = 0,95.d_{nom}$
- if d_{nom} > 1000 mm $d = d_{nom}$ - 50 mm

Where d_{nom} is the nominal diameter of the pile.

2.4   Verification by the partial factor method

2.4.1 General

(1) The rules for the partial factor method are given in EN 1990 Section 6.

2.4.2 Design values

2.4.2.1 Partial factor for shrinkage action

(1) Where consideration of shrinkage actions is required for ultimate limit state a partial factor, γ_{SH}, should be used.

> **Note:** The value of γ_{SH} for use in a Country may be found in its National Annex. The recommended value is 1,0.

2.4.2.2 Partial factors for prestress

(1) Prestress in most situations is intended to be favourable and for the ultimate limit state verification the value of $\gamma_{P,fav}$ should be used. The design value of prestress may be based on the mean value of the prestressing force (see EN 1990 Section 4).

> **Note:** The value of $\gamma_{P,fav}$ for use in a Country may be found in its National Annex. The recommended value for persistent and transient design situations is 1,0. This value may also be used for fatigue verification.

(2) In the verification of the limit state for stability with external prestress, where an increase of the value of prestress can be unfavourable, $\gamma_{P,unfav}$ should be used.

> **Note:** The value of $\gamma_{P,unfav}$ in the stability limit state for use in a Country may be found in its National Annex. The recommended value for global analysis is 1,3.

(3) In the verification of local effects $\gamma_{P,unfav}$ should also be used.

> **Note:** The value of $\gamma_{P,unfav}$ for local effects for use in a Country may be found in its National Annex. The recommended value is 1,2. The local effects of the anchorage of pre-tensioned tendons are considered in 8.10.2.

2.4.2.3 Partial factor for fatigue loads

(1) The partial factor for fatigue loads is $\gamma_{F,fat}$.

> **Note:** The value of $\gamma_{F,fat}$ for use in a Country may be found in its National Annex. The recommended value is 1,0.

2.4.2.4 Partial factors for materials

(1) Partial factors for materials for ultimate limit states, γ_C and γ_S should be used.

> **Note:** The values of γ_C and γ_S for use in a Country may be found in its National Annex. The recommended values for 'persistent & transient' and 'accidental, design situations are given in Table 2.1N. These are not valid for fire design for which reference should be made to EN 1992-1-2.
>
> For fatigue verification the partial factors for persistent design situations given in Table 2.1N are recommended for the values of $\gamma_{C,fat}$ and $\gamma_{S,fat.}$

Table 2.1N: Partial factors for materials for ultimate limit states

Design situations	γ_C for concrete	γ_S for reinforcing steel	γ_S for prestressing steel
Persistent & Transient	1,5	1,15	1,15
Accidental	1,2	1,0	1,0

(2) The values for partial factors for materials for serviceability limit state verification should be taken as those given in the particular clauses of this Eurocode.

> **Note:** The values of γ_C and γ_S in the serviceability limit state for use in a Country may be found in its National Annex. The recommended value for situations not covered by particular clauses of this Eurocode is 1,0.

(3) Lower values of γ_C and γ_S may be used if justified by measures reducing the uncertainty in the calculated resistance.

> **Note:** Information is given in Informative Annex A.

2.4.2.5 Partial factors for materials for foundations

(1) Design values of strength properties of the ground should be calculated in accordance with EN 1997.

(2) The partial factor for concrete γ_C given in 2.4.2.4 (1) should be multiplied by a factor, k_f, for calculation of design resistance of cast in place piles without permanent casing.

Note: The value of k_f for use in a Country may be found in its National Annex. The recommended value is 1,1.

2.4.3 Combinations of actions

(1) The general formats for combinations of actions for the ultimate and serviceability limit states are given in EN 1990, Section 6.

Note 1: Detailed expressions for combinations of actions are given in the normative annexes of EN 1990, i.e. Annex A1 for buildings, A2 for bridges, etc. with relevant recommended values for partial factors and representative values of actions given in the notes.

Note 2: Combination of actions for fatigue verification is given in 6.8.3.

(2) For each permanent action either the lower or the upper design value (whichever gives the more unfavourable effect) should be applied throughout the structure (e.g. self-weight in a structure).

Note: There may be some exceptions to this rule (e.g. in the verification of static equilibrium, see EN 1990 Section 6). In such cases a different set of partial factors (Set A) may be used. An example valid for buildings is given in Annex A1 of EN 1990.

2.4.4 Verification of static equilibrium - EQU

(1) The reliability format for the verification of static equilibrium also applies to design situations of EQU, such as holding down devices or the verification of the uplift of bearings for continuous beams.

Note: Information is given in Annex A of EN 1990.

2.5 Design assisted by testing

(1) The design of structures or structural elements may be assisted by testing.

Note: Information is given in Section 5 and Annex D of EN 1990.

2.6 Supplementary requirements for foundations

(1)P Where ground-structure interaction has significant influence on the action effects in the structure, the properties of the soil and the effects of the interaction shall be taken into account in accordance with EN 1997-1.

(2) Where significant differential settlements are likely their influence on the action effects in the structure should be checked.

Note 1: Annex G may be used to model the soil -structure interaction.

Note 2: Simple methods ignoring the effects of ground deformation are normally appropriate for the majority of structural designs.

(3) Concrete foundations should be sized in accordance with EN 1997-1.

(4) Where relevant, the design should include the effects of phenomena such as subsidence, heave, freezing, thawing, erosion, etc.

2.7   Requirements for fastenings

(1) The local and structural effects of fasteners should be considered.

> **Note:** The requirements for the design of fastenings are given in the Technical Specification 'Design of Fastenings for Use in Concrete' (under development). This Technical Specification will cover the design of the following types of fasteners:
> cast-in fasteners such as:
> - headed anchors,
> - channel bars,
> and post-installed fasteners such as:
> - expansion anchors,
> - undercut anchors,
> - concrete screws,
> - bonded anchors,
> - bonded expansion anchors and
> - bonded undercut anchors.
>
> The performance of fasteners should comply with the requirements of a CEN Standard or should be demonstrated by a European Technical Approval.
>
> The Technical Specification 'Design of Fastenings' for Use in Concrete' includes the local transmission of loads into the structure.
>
> In the design of the structure the loads and additional design requirements given in Annex A of that Technical Specification should be taken into account.

SECTION 3   MATERIALS

3.1   Concrete

3.1.1   General

(1)P The following clauses give principles and rules for normal and high strength concrete.

(2) Rules for lightweight aggregate concrete are given in Section 11.

3.1.2 Strength

(1)P The compressive strength of concrete is denoted by concrete strength classes which relate to the characteristic (5%) cylinder strength f_{ck}, or the cube strength $f_{ck,cube}$, in accordance with EN 206-1.

(2)P The strength classes in this code are based on the characteristic cylinder strength f_{ck} determined at 28 days with a maximum value of C_{max}.

> **Note:** The value of C_{max} for use in a Country may be found in its National Annex. The recommended value is C90/105.

(3) The characteristic strengths for f_{ck} and the corresponding mechanical characteristics necessary for design, are given in Table 3.1.

(4) In certain situations (e.g. prestressing) it may be appropriate to assess the compressive strength for concrete before or after 28 days, on the basis of test specimens stored under other conditions than prescribed in EN 12390.

If the concrete strength is determined at an age t > 28 days the values α_{cc} and α_{ct} defined in 3.1.6 (1)P and 3.1.6 (2)P should be reduced by a factor k_t.

> **Note:** The value of k_t for use in a Country may be found in its National Annex. The recommended value is 0,85.

(5) It may be required to specify the concrete compressive strength, $f_{ck}(t)$, at time t for a number of stages (e.g. demoulding, transfer of prestress), where

$\quad\quad f_{ck}(t) = f_{cm}(t) - 8$ (MPa) for $\quad\quad$ 3 < t < 28 days.
$\quad\quad f_{ck}(t) = f_{ck}$ $\quad\quad\quad\quad$ for $\quad\quad$ $t \geq 28$ days

More precise values should be based on tests especially for $t \leq 3$ days

(6) The compressive strength of concrete at an age t depends on the type of cement, temperature and curing conditions. For a mean temperature of 20°C and curing in accordance with EN 12390 the compressive strength of concrete at various ages $f_{cm}(t)$ may be estimated from Expressions (3.1) and (3.2).

$\quad\quad f_{cm}(t) = \beta_{cc}(t) \, f_{cm}$ $\hfill$ (3.1)

$\quad\quad$ with

$$\beta_{cc}(t) = \exp\left\{ s \left[1 - \left(\frac{28}{t} \right)^{1/2} \right] \right\}$$ $\hfill$ (3.2)

$\quad\quad$ where:

$\quad\quad\quad f_{cm}(t)$ $\quad$ is the mean concrete compressive strength at an age of t days

f_{cm} is the mean compressive strength at 28 days according to Table 3.1

$\beta_{cc}(t)$ is a coefficient which depends on the age of the concrete t

t is the age of the concrete in days

s is a coefficient which depends on the type of cement:

= 0,20 for cement of strength Classes CEM 42,5 R, CEM 52,5 N and CEM 52,5 R (Class R)

= 0,25 for cement of strength Classes CEM 32,5 R, CEM 42,5 N (Class N)

= 0,38 for cement of strength Classes CEM 32,5 N (Class S)

Note: exp{ } has the same meaning as $e^{(\ )}$

Where the concrete does not conform with the specification for compressive strength at 28 days the use of Expressions (3.1) and (3.2) is not appropriate.

This clause should not be used retrospectively to justify a non conforming reference strength by a later increase of the strength.

For situations where heat curing is applied to the member see 10.3.1.1 (3).

(7)P The tensile strength refers to the highest stress reached under concentric tensile loading. For the flexural tensile strength reference should be made to 3.1.8 (1).

(8)   Where the tensile strength is determined as the splitting tensile strength, $f_{ct,sp}$, an approximate value of the axial tensile strength, f_{ct}, may be taken as:

$$f_{ct} = 0{,}9 f_{ct,sp} \tag{3.3}$$

(9) The development of tensile strength with time is strongly influenced by curing and drying conditions as well as by the dimensions of the structural members. As a first approximation it may be assumed that the tensile strength $f_{ctm}(t)$ is equal to:

$$f_{ctm}(t) = (\beta_{cc}(t))^{\alpha}\cdot f_{ctm} \tag{3.4}$$

where $\beta_{cc}(t)$ follows from Expression (3.2) and

$\alpha = 1$ for $t < 28$

$\alpha = 2/3$ for $t \geq 28$. The values for f_{ctm} are given in Table 3.1.

Note: Where the development of the tensile strength with time is important it is recommended that tests are carried out taking into account the exposure conditions and the dimensions of the structural member.

3.1.3 Elastic deformation

(1) The elastic deformations of concrete largely depend on its composition (especially the aggregates). The values given in this Standard should be regarded as indicative for general applications. However, they should be specifically assessed if the structure is likely to be sensitive to deviations from these general values.

(2) The modulus of elasticity of a concrete is controlled by the moduli of elasticity of its components. Approximate values for the modulus of elasticity E_{cm}, secant value between $\sigma_c = 0$ and $0{,}4 f_{cm}$, for concretes with quartzite aggregates, are given in Table 3.1. For limestone and sandstone aggregates the value should be reduced by 10% and 30% respectively. For basalt aggregates the value should be increased by 20%.

Note: A Country's National Annex may refer to non-contradictory complementary information.

Table 3.1 Strength and deformation characteristics for concrete

	Strength classes for concrete														Analytical relation / Explanation
f_{ck} (MPa)	12	16	20	25	30	35	40	45	50	55	60	70	80	90	
$f_{ck,cube}$ (MPa)	15	20	25	30	37	45	50	55	60	67	75	85	95	105	
f_{cm} (MPa)	20	24	28	33	38	43	48	53	58	63	68	78	88	98	$f_{cm} = f_{ck}+8$ (MPa)
f_{ctm} (MPa)	1,6	1,9	2,2	2,6	2,9	3,2	3,5	3,8	4,1	4,2	4,4	4,6	4,8	5,0	$f_{ctm}=0,30 \times f_{ck}^{(2/3)} \leq$ C50/60 $f_{ctm}=2,12 \cdot \ln(1+(f_{cm}/10))$ > C50/60
$f_{ctk,0.05}$ (MPa)	1,1	1,3	1,5	1,8	2,0	2,2	2,5	2,7	2,9	3,0	3,1	3,2	3,4	3,5	$f_{ctk;0,05} = 0,7 \times f_{ctm}$ 5% fractile
$f_{ctk,0.95}$ (MPa)	2,0	2,5	2,9	3,3	3,8	4,2	4,6	4,9	5,3	5,5	5,7	6,0	6,3	6,6	$f_{ctk;0,95} = 1,3 \times f_{ctm}$ 95% fractile
E_{cm} (GPa)	27	29	30	31	33	34	35	36	37	38	39	41	42	44	$E_{cm} = 22[(f_{cm})/10]^{0,3}$ (f_{cm} in MPa)
ε_{c1} (‰)	1,8	1,9	2,0	2,1	2,2	2,25	2,3	2,4	2,45	2,5	2,6	2,7	2,8	2,8	see Figure 3.2 $\varepsilon_{c1}(‰) = 0,7\, f_{cm}^{0,31} < 2,8$
ε_{cu1} (‰)	3,5									3,2	3,0	2,8	2,8	2,8	see Figure 3.2 for $f_{ck} \geq 50$ Mpa $\varepsilon_{cu1}(‰)=2,8+27[(98-f_{cm})/100]^4$
ε_{c2} (‰)	2,0									2,2	2,3	2,4	2,5	2,6	see Figure 3.3 for $f_{ck} \geq 50$ Mpa $\varepsilon_{c2}(‰)=2,0+0,085(f_{ck}-50)^{0,53}$
ε_{cu2} (‰)	3,5									3,1	2,9	2,7	2,6	2,6	see Figure 3.3 for $f_{ck} \geq 50$ Mpa $\varepsilon_{cu2}(‰)=2,6+35[(90-f_{ck})/100]^4$
n	2,0									1,75	1,6	1,45	1,4	1,4	for $f_{ck} \geq 50$ Mpa $n=1,4+23,4[(90-f_{ck})/100]^4$
ε_{c3} (‰)	1,75									1,8	1,9	2,0	2,2	2,3	see Figure 3.4 for $f_{ck} \geq 50$ Mpa $\varepsilon_{c3}(‰)=1,75+0,55[(f_{ck}-50)/40]$
ε_{cu3} (‰)	3,5									3,1	2,9	2,7	2,6	2,6	see Figure 3.4 for $f_{ck} \geq 50$ Mpa $\varepsilon_{cu3}(‰)=2,6+35[(90-f_{ck})/100]^4$

(3) Variation of the modulus of elasticity with time can be estimated by:

$$E_{cm}(t) = (f_{cm}(t) / f_{cm})^{0,3} \, E_{cm} \tag{3.5}$$

where $E_{cm}(t)$ and $f_{cm}(t)$ are the values at an age of t days and E_{cm} and f_{cm} are the values determined at an age of 28 days. The relation between $f_{cm}(t)$ and f_{cm} follows from Expression (3.1).

(4) Poisson's ratio may be taken equal to 0,2 for uncracked concrete and 0 for cracked concrete.

(5) Unless more accurate information is available, the linear coefficient of thermal expansion may be taken equal to $10 \cdot 10^{-6} \, K^{-1}$.

3.1.4 Creep and shrinkage

(1)P Creep and shrinkage of the concrete depend on the ambient humidity, the dimensions of the element and the composition of the concrete. Creep is also influenced by the maturity of the concrete when the load is first applied and depends on the duration and magnitude of the loading.

(2) The creep coefficient, $\varphi(t,t_0)$ is related to E_c, the tangent modulus, which may be taken as $1,05 \, E_{cm}$. Where great accuracy is not required, the value found from Figure 3.1 may be considered as the creep coefficient, provided that the concrete is not subjected to a compressive stress greater than $0,45 \, f_{ck} \, (t_0)$ at an age t_0, the age of concrete at the time of loading.

> **Note:** For further information, including the development of creep with time, Annex B may be used.

(3) The creep deformation of concrete $\varepsilon_{cc}(\infty,t_0)$ at time $t = \infty$ for a constant compressive stress σ_c applied at the concrete age t_0, is given by:

$$\varepsilon_{cc}(\infty,t_0) = \varphi\,(\infty,t_0). \, (\sigma_c / E_c) \tag{3.6}$$

(4) When the compressive stress of concrete at an age t_0 exceeds the value $0,45 \, f_{ck}(t_0)$ then creep non-linearity should be considered. Such a high stress can occur as a result of pretensioning, e.g. in precast concrete members at tendon level. In such cases the non-linear notional creep coefficient should be obtained as follows:

$$\varphi_k(\infty, t_0) = \varphi\,(\infty, t_0) \exp\,(1,5\,(k_\sigma - 0,45)) \tag{3.7}$$

where:
$\varphi_k(\infty, t_0)$ is the non-linear notional creep coefficient, which replaces $\varphi\,(\infty, t_0)$
k_σ is the stress-strength ratio $\sigma_c/f_{cm}(t_0)$, where σ_c is the compressive stress and $f_{cm}(t_0)$ is the mean concrete compressive strength at the time of loading.

a)   inside conditions - RH = 50%
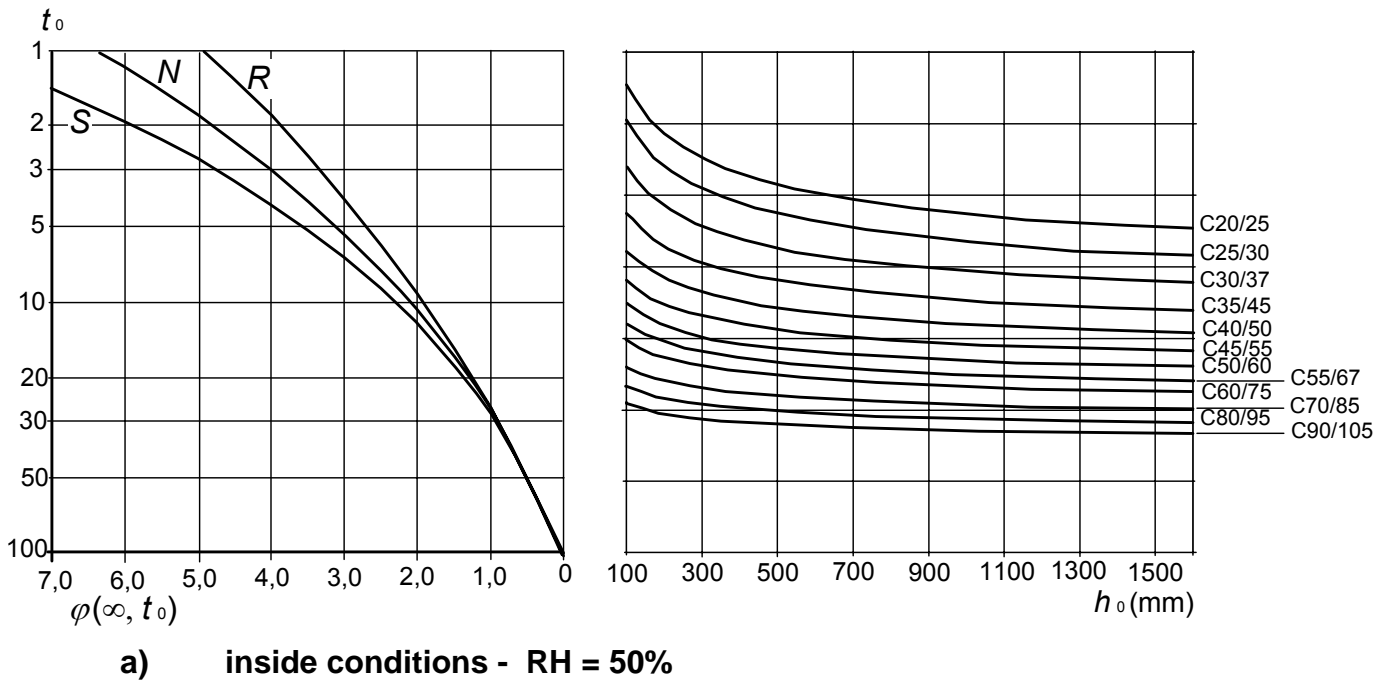

Note:
- intersection point between lines 4 and 5 can also be above point 1
- for t_0 > 100 it is sufficiently accurate to assume t_0 = 100 (and use the tangent line)

b) outside conditions - RH = 80%
Figure 3.1: Method for determining the creep coefficient $\varphi(\infty, t_0)$ for concrete under normal environmental conditions

(5) The values given in Figure 3.1 are valid for ambient temperatures between -40°C and +40°C and a mean relative humidity between RH = 40% and RH = 100%. The following symbols are used:

$\varphi\,(\infty, t_0)$ is the final creep coefficient

t_0 is the age of the concrete at time of loading in days

h_0 is the notional size = $2A_c\,/u$, where A_c is the concrete cross-sectional area and u is the perimeter of that part which is exposed to drying

S is Class S, according to 3.1.2 (6)

N is Class N, according to 3.1.2 (6)

R is Class R, according to 3.1.2 (6)

(6) The total shrinkage strain is composed of two components, the drying shrinkage strain and the autogenous shrinkage strain. The drying shrinkage strain develops slowly, since it is a function of the migration of the water through the hardened concrete. The autogenous shrinkage strain develops during hardening of the concrete: the major part therefore develops in the early days after casting. Autogenous shrinkage is a linear function of the concrete strength. It should be considered specifically when new concrete is cast against hardened concrete. Hence the values of the total shrinkage strain ε_{cs} follow from

$$\varepsilon_{cs} = \varepsilon_{cd} + \varepsilon_{ca} \tag{3.8}$$

where:

ε_{cs} is the total shrinkage strain

ε_{cd} is the drying shrinkage strain

ε_{ca} is the autogenous shrinkage strain

The final value of the drying shrinkage strain, $\varepsilon_{cd,\infty}$ is equal to $k_h \cdot \varepsilon_{cd,0}$. $\varepsilon_{cd,0}$ may be taken from Table 3.2 (expected mean values, with a coefficient of variation of about 30%).

Note: The formula for $\varepsilon_{cd,0}$ is given in Annex B.

Table 3.2 Nominal unrestrained drying shrinkage values $\varepsilon_{cd,0}$ (in $^0/_{00}$) for concrete with cement CEM Class N

$f_{ck}/f_{ck,cube}$ (MPa)	Relative Humidity (in $^0/_0$)					
	20	40	60	80	90	100
20/25	0.62	0.58	0.49	0.30	0.17	0.00
40/50	0.48	0.46	0.38	0.24	0.13	0.00
60/75	0.38	0.36	0.30	0.19	0.10	0.00
80/95	0.30	0.28	0.24	0.15	0.08	0.00
90/105	0.27	0.25	0.21	0.13	0.07	0.00

The development of the drying shrinkage strain in time follows from:

$$\varepsilon_{cd}(t) = \beta_{ds}(t, t_s) \cdot k_h \cdot \varepsilon_{cd,0} \tag{3.9}$$

where

k_h is a coefficient depending on the notional size h_0 according to Table 3.3

Table 3.3 Values for k_h in Expression (3.9)

h_0	k_h
100	1.0
200	0.85
300	0.75
≥ 500	0.70

$$\beta_{ds}(t,t_s) = \frac{(t - t_s)}{(t - t_s) + 0{,}04\sqrt{h_0^3}}$$
(3.10)

where:

t is the age of the concrete at the moment considered, in days

t_s is the age of the concrete (days) at the beginning of drying shrinkage (or swelling). Normally this is at the end of curing.

h_0 is the notional size (mm) of the cross-section

= $2A_c/u$

where:

A_c is the concrete cross-sectional area

u is the perimeter of that part of the cross section which is exposed to drying

The autogenous shrinkage strain follows from:

$$\varepsilon_{ca}(t) = \beta_{as}(t)\,\varepsilon_{ca}(\infty)$$
(3.11)

where:

$$\varepsilon_{ca}(\infty) = 2{,}5\,(f_{ck} - 10)\,10^{-6}$$
(3.12)

and

$$\beta_{as}(t) = 1 - \exp\left(- 0{,}2t^{\,0{,}5}\right)$$
(3.13)

where t is given in days.

3.1.5 Stress-strain relation for non-linear structural analysis

(1) The relation between σ_c and ε_c shown in Figure 3.2 (compressive stress and shortening strain shown as absolute values) for short term uniaxial loading is described by the Expression (3.14):

$$\frac{\sigma_c}{f_{cm}} = \frac{k\eta - \eta^2}{1 + (k - 2)\eta}$$
(3.14)

where:

$\eta = \varepsilon_c/\varepsilon_{c1}$

ε_{c1} is the strain at peak stress according to Table 3.1

k = $1{,}05\,E_{cm} \times |\varepsilon_{c1}|/f_{cm}$ (f_{cm} according to Table 3.1)

Expression (3.14) is valid for $0 < |\varepsilon_c| < |\varepsilon_{cu1}|$ where ε_{cu1} is the nominal ultimate strain.

(2) Other idealised stress-strain relations may be applied, if they adequately represent the behaviour of the concrete considered.
Figure 3.2: **Schematic representation of the stress-strain relation for structural analysis (the use 0,4f_{cm} for the definition of E_{cm} is approximate).**

3.1.6 Design compressive and tensile strengths

(1)P The value of the design compressive strength is defined as

$$f_{cd} = \alpha_{cc}\, f_{ck}\, /\, \gamma_C \tag{3.15}$$

where:

γ_C is the partial safety factor for concrete, see 2.4.2.4, and

α_{cc} is the coefficient taking account of long term effects on the compressive strength and of unfavourable effects resulting from the way the load is applied.

Note: The value of α_{cc} for use in a Country should lie between 0,8 and 1,0 and may be found in its National Annex. The recommended value is 1.

(2)P The value of the design tensile strength, f_{ctd}, is defined as

$$f_{ctd} = \alpha_{ct}\, f_{ctk,0,05}\, /\, \gamma_C \tag{3.16}$$

where:

γ_C is the partial safety factor for concrete, see 2.4.2.4, and

α_{ct} is a coefficient taking account of long term effects on the tensile strength and of unfavourable effects, resulting from the way the load is applied.

Note: The value of α_{ct} for use in a Country may be found in its National Annex. The recommended value is 1,0.

3.1.7 Stress-strain relations for the design of cross-sections

(1) For the design of cross-sections, the following stress-strain relationship may be used, see Figure 3.3 (compressive strain shown positive):

$$\sigma_c = f_{cd} \left[1 - \left(1 - \frac{\varepsilon_c}{\varepsilon_{c2}} \right)^n \right] \quad \text{for} \quad 0 \le \varepsilon_c \le \varepsilon_{c2}$$ (3.17)

$$\sigma_c = f_{cd} \quad \textit{for} \quad \varepsilon_{c2} \le \varepsilon_c \le \varepsilon_{cu2}$$ (3.18)

where:

   n is the exponent according to Table 3.1

   ε_{c2} is the strain at reaching the maximum strength according to Table 3.1

   ε_{cu2} is the ultimate strain according to Table 3.1
Figure 3.3: Parabola-rectangle diagram for concrete under compression.

(2) Other simplified stress-strain relationships may be used if equivalent to or more conservative than the one defined in (1), for instance bi-linear according to Figure 3.4 (compressive stress and shortening strain shown as absolute values) with values of ε_{c3} and ε_{cu3} according to Table 3.1.
Figure 3.4: Bi-linear stress-strain relation.

(3) A rectangular stress distribution (as given in Figure 3.5) may be assumed. The factor λ,

35

defining the effective height of the compression zone and the factor η, defining the effective strength, follow from:

$\lambda = 0,8$ for $f_{ck} \leq 50$ MPa   (3.19)

$\lambda = 0,8 - (f_{ck} - 50)/400$ for $50 < f_{ck} \leq 90$ MPa   (3.20)

and

$\eta = 1,0$ for $f_{ck} \leq 50$ MPa   (3.21)

$\eta = 1,0 - (f_{ck} - 50)/200$ for $50 < f_{ck} \leq 90$ MPa   (3.22)

Note: If the width of the compression zone decreases in the direction of the extreme compression fibre, the value $\eta\, f_{cd}$ should be reduced by 10%.
Figure 3.5: Rectangular stress distribution

3.1.8 Flexural tensile strength

(1) The mean flexural tensile strength of reinforced concrete members depends on the mean axial tensile strength and the depth of the cross-section. The following relationship may be used:

$$f_{ctm,fl} = \max \{(1,6 - h/1000)f_{ctm}; f_{ctm} \} \qquad (3.23)$$

where:
    h is the total member depth in mm
    f_{ctm} is the mean axial tensile strength following from Table 3.1.

The relation given in Expression (3.23) also applies for the characteristic tensile strength values.

3.1.9 Confined concrete

(1) Confinement of concrete results in a modification of the effective stress-strain relationship: higher strength and higher critical strains are achieved. The other basic material characteristics may be considered as unaffected for design.

(2) In the absence of more precise data, the stress-strain relation shown in Figure 3.6 (compressive strain shown positive) may be used, with increased characteristic strength and strains according to:

$$f_{ck,c} = f_{ck}(1,000 + 5,0\ \sigma_2/f_{ck}) \qquad \text{for } \sigma_2 \leq 0,05f_{ck} \qquad (3.24)$$

$$f_{ck,c} = f_{ck}\ (1{,}125 + 2{,}50\ \sigma_2/f_{ck}) \quad \text{for}\ \sigma_2 > 0{,}05 f_{ck} \tag{3.25}$$

$$\varepsilon_{c2,c} = \varepsilon_{c2}\ (f_{ck,c}/f_{ck})^2 \tag{3.26}$$

$$\varepsilon_{cu2,c} = \varepsilon_{cu2} + 0{,}2\ \sigma_2/f_{ck} \tag{3.27}$$

where σ_2 ($= \sigma_3$) is the effective lateral compressive stress at the ULS due to confinement and ε_{c2} and ε_{cu2} follow from Table 3.1. Confinement can be generated by adequately closed links or cross-ties, which reach the plastic condition due to lateral extension of the concrete.
Figure 3.6: Stress-strain relationship for confined concrete

3.2   Reinforcing steel

3.2.1 General

(1)P The following clauses give principles and rules for reinforcement which is in the form of bars, de-coiled rods, welded fabric and lattice girders. They do not apply to specially coated bars.

(2)P The requirements for the properties of the reinforcement are for the material as placed in the hardened concrete. If site operations can affect the properties of the reinforcement, then those properties shall be verified after such operations.

(3)P Where other steels are used, which are not in accordance with EN10080, the properties shall be verified to be in accordance with 3.2.2 to 3.2.6 and Annex C.

(4)P The required properties of reinforcing steels shall be verified using the testing procedures in accordance with EN 10080.

> **Note:** EN 10080 refers to a yield strength R_e, which relates to the characteristic, minimum and maximum values based on the long-term quality level of production. In contrast f_{yk} is the characteristic yield stress based on only that reinforcement used in a particular structure. There is no direct relationship between f_{yk} and the characteristic R_e. However the methods of evaluation and verification of yield strength given in EN 10080 provide a sufficient check for obtaining f_{yk}.

(5) The application rules relating to lattice girders (see EN 10080 for definition) apply only to those made with ribbed bars. Lattice girders made with other types of reinforcement may be given in an appropriate European Technical Approval.

3.2.2 Properties

(1)P The behaviour of reinforcing steel is specified by the following properties:

- yield strength (f_{yk} or $f_{0,2k}$)
- maximum actual yield strength ($f_{y,max}$)
- tensile strength (f_t)
- ductility (ε_{uk} and f_t/f_{yk})
- bendability
- bond characteristics (f_R: See Annex C)
- section sizes and tolerances
- fatigue strength
- weldability
- shear and weld strength for welded fabric and lattice girders

(2)P This Eurocode applies to ribbed and weldable reinforcement, including fabric. The permitted welding methods are given in Table 3.4.

Note 1: The properties of reinforcement required for use with this Eurocode are given in Annex C.

Note 2: The properties and rules for the use of indented bars with precast concrete products may be found in the relevant product standard.

(3)P The application rules for design and detailing in this Eurocode are valid for a specified yield strength range, f_{yk} = 400 to 600 MPa.

Note: The upper limit of f_{yk} within this range for use within a Country may be found in its National Annex.

(4)P The surface characteristics of ribbed bars shall be such to ensure adequate bond with the concrete.

(5)   Adequate bond may be assumed by compliance with the specification of projected rib area, f_R.

Note: Minimum values of the relative rib area, f_R, are given in the Annex C.

(6)P The reinforcement shall have adequate bendability to allow the use of the minimum mandrel diameters specified in Table 8.1 and to allow rebending to be carried out.

Note: For bend and rebend requirements see Annex C.

3.2.3 Strength

(1)P The yield strength f_{yk} (or the 0,2% proof stress, $f_{0,2k}$) and the tensile strength f_{tk} are defined respectively as the characteristic value of the yield load, and the characteristic maximum load in direct axial tension, each divided by the nominal cross sectional area.

3.2.4 Ductility characteristics

(1)P The reinforcement shall have adequate ductility as defined by the ratio of tensile strength to the yield stress, $(f_t/f_y)_k$ and the elongation at maximum force, ε_{uk} .

(2) Figure 3.7 shows stress-strain curves for typical hot rolled and cold worked steel.

Note: Values of $(f_t/f_y)_k$ and ε_{uk} for Class A, B and C are given in Annex C.
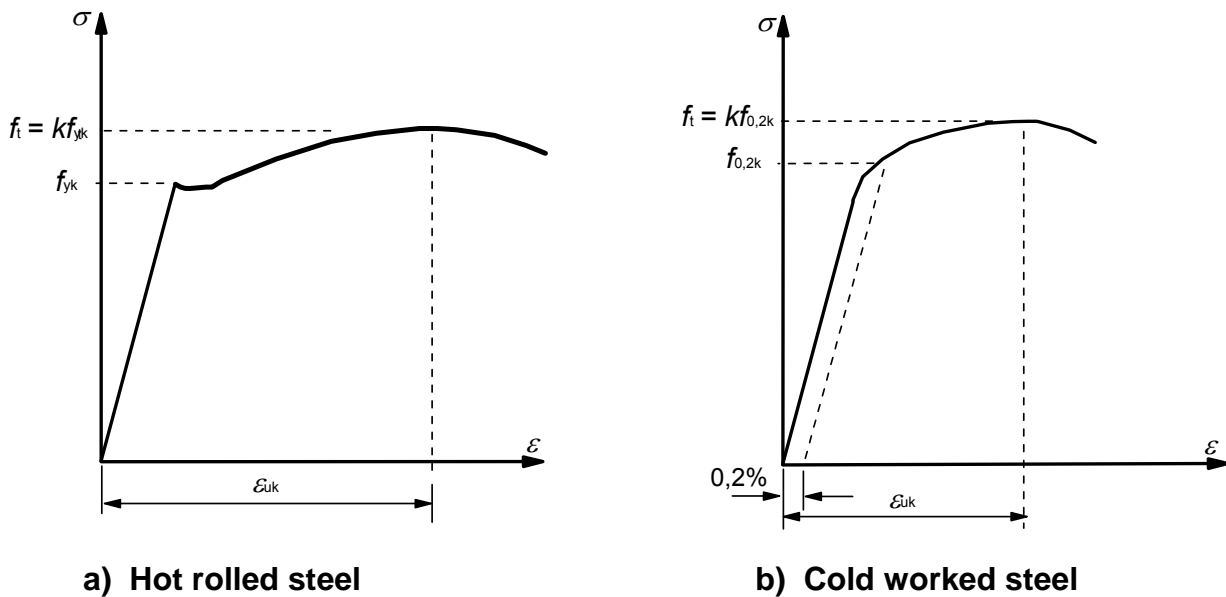

a) Hot rolled steel   **b) Cold worked steel**

Figure 3.7: Stress-strain diagrams of typical reinforcing steel (absolute values are shown for tensile stress and strain)

3.2.5 Welding

(1)P Welding processes for reinforcing bars shall be in accordance with Table 3.4 and the weldability shall be in accordance with EN10080.

Table 3.4: Permitted welding processes and examples of application

Loading case	Welding method	Bars in tension[1]	Bars in compression[1]
Predominantly static (see 6.8.1 (2))	flash-welding	butt joint	
	manual metal arc welding and metal arc welding with filling electrode	butt joint with $\phi \geq 20$ mm, splice, lap, cruciform joints[3], joint with other steel members	
	metal arc active welding[2]	splice, lap, cruciform[3] joints & joint with other steel members	
		-	butt joint with $\phi \geq 20$ mm
	friction welding	butt joint, joint with other steels	
	resistance spot welding	lap joint[4] cruciform joint[2, 4]	
Not predominantly static (see 6.8.1 (2))	flash-welding	butt joint	
	manual metal arc welding	-	butt joint with $\phi \geq 14$mm
	metal arc active welding[2]	-	butt joint with $\phi \geq 14$mm
	resistance spot welding	lap joint[4] cruciform joint[2, 4]	
Notes:			
1. Only bars with approximately the same nominal diameter may be welded together. 2. Permitted ratio of mixed diameter bars $\geq 0{,}57$ 3. For bearing joints $\phi \leq 16$ mm 4. For bearing joints $\phi \leq 28$ mm			

(2)P All welding of reinforcing bars shall be carried out in accordance with EN ISO 17760.

(3)P The strength of the welded joints along the anchorage length of welded fabric shall be sufficient to resist the design forces.

(4) The strength of the welded joints of welded fabric may be assumed to be adequate if each welded joint can withstand a shearing force not less than 25% of a force equivalent to the specified characteristic yield stress times the nominal cross sectional area. This force should be based on the area of the thicker wire if the two are different.

3.2.6 Fatigue

(1)P Where fatigue strength is required it shall be verified in accordance with EN 10080.

> **Note :** Information is given in Annex C.

3.2.7 Design assumptions

(1) Design should be based on the nominal cross-section area of the reinforcement and the design values derived from the characteristic values given in 3.2.2.

(2) For normal design, either of the following assumptions may be made (see Figure 3.8):

a) an inclined top branch with a strain limit of ε_{ud} and a maximum stress of kf_{yk}/γ_s at ε_{uk}, where $k = (f_t/f_y)_k$,

b) a horizontal top branch without the need to check the strain limit.

> **Note 1:** The value of ε_{ud} for use in a Country may be found in its National Annex. The recommended value is $0,9\varepsilon_{uk}$

> **Note 2:** The value of $(f_t/f_y)_k$ is given in Annex C.
Figure 3.8: Idealised and design stress-strain diagrams for reinforcing steel (for tension and compression)

(3) The mean value of density may be assumed to be 7850 kg/m^3.

(4) The design value of the modulus of elasticity, E_s may be assumed to be 200 GPa.

3.3   Prestressing steel

3.3.1   General

(1)P This clause applies to wires, bars and strands used as prestressing tendons in concrete structures.

(2)P Prestressing tendons shall have an acceptably low level of susceptibility to stress corrosion.

(3) The level of susceptibility to stress corrosion may be assumed to be acceptably low if the prestressing tendons comply with the criteria specified in EN 10138 or given in an appropriate European Technical Approval.

(4) The requirements for the properties of the prestressing tendons are for the materials as placed in their final position in the structure. Where the methods of production, testing and attestation of conformity for prestressing tendons are in accordance with EN 10138 or given in an appropriate European Technical Approval it may be assumed that the requirements of this Eurocode are met.

(5)P For steels complying with this Eurocode, tensile strength, 0,1% proof stress, and elongation at maximum load are specified in terms of characteristic values; these values are designated respectively f_{pk}, $f_{p0,1k}$ and ε_{uk}.

> **Note:**   EN 10138 refers to the characteristic, minimum and maximum values based on the long-term quality level of production. In contrast $f_{p0,1k}$ and f_{pk} are the characteristic proof stress and tensile strength based on only that prestressing steel required for the structure. There is no direct relationship between the two sets of values. However the characteristic values for 0,1% proof force, $F_{p0,1k}$ divided by the cross-section area, S_n given in EN 10138 together with the methods for evaluation and verification provide a sufficient check for obtaining the value of $f_{p0,1k}$.

(6) Where other steels are used, which are not in accordance with EN 10138, the properties may be given in an appropriate European Technical Approval.

(7)P Each product shall be clearly identifiable with respect to the classification system in 3.3.2 (2)P.

(8)P The prestressing tendons shall be classified for relaxation purposes according to 3.3.2 (4)P or given in an appropriate European Technical Approval.

(9)P Each consignment shall be accompanied by a certificate containing all the information necessary for its identification with regard to (i) - (iv) in 3.3.2 (2)P and additional information where necessary.

(10)P There shall be no welds in wires and bars. Individual wires of strands may contain staggered welds made only before cold drawing.

(11)P For coiled prestressing tendons, after uncoiling a length of wire or strand the maximum bow height shall comply with EN 10138 unless given in an appropriate European Technical Approval.

3.3.2 Properties

(1)P   The properties of prestressing steel are given in EN 10138, Parts 2 to 4 or European Technical Approval.

(2)P The prestressing tendons (wires, strands and bars) shall be classified according to:
   (i) Strength, denoting the value of the 0,1% proof stress ($f_{p0,1k}$) and the value of the ratio of tensile strength to proof strength (f_{pk} /$f_{p0,1k}$) and elongation at maximum load (ε_{uk})
   (ii) Class, indicating the relaxation behaviour
   (iii) Size
   (iv) Surface characteristics.

(3)P The actual mass of the prestressing tendons shall not differ from the nominal mass by more than the limits specified in EN 10138 or given in an appropriate European Technical Approval.

(4)P In this Eurocode, three classes of relaxation are defined:
   -   Class 1: wire or strand - ordinary relaxation
   -   Class 2: wire or strand - low relaxation
   -   Class 3: hot rolled and processed bars

   Note: Class 1 is not covered by EN 10138.

(5) The design calculations for the losses due to relaxation of the prestressing steel should be based on the value of ρ_{1000}, the relaxation loss (in %) at 1000 hours after tensioning and at a mean temperature of 20 °C (see EN 10138 for the definition of the isothermal relaxation test).

   Note: The value of ρ_{1000} is expressed as a percentage ratio of the initial stress and is obtained for an initial stress equal to $0,7f_p$, where f_p is the actual tensile strength of the prestressing steel samples. For design calculations, the characteristic tensile strength (f_{pk}) is used and this has been taken into account in the following expressions.

(6) The values for ρ_{1000} can be either assumed equal to 8% for Class 1, 2,5% for Class 2, and 4% for Class 3, or taken from the certificate.

(7) The relaxation loss may be obtained from the manufacturers test certificates or defined as the percentage ratio of the variation of the prestressing stress over the initial prestressing stress, should be determined by applying one of the Expressions below. Expressions (3.28) and (3.29) apply for wires or strands for ordinary prestressing and low relaxation tendons respectively, whereas Expression (3.30) applies for hot rolled and processed bars.

Class 1 $$\frac{\Delta\sigma_{pr}}{\sigma_{pi}} = 5,39 \; \rho_{1000} \; e^{6,7\,\mu} \left(\frac{t}{1000}\right)^{0,75\,(1-\mu)} 10^{-5} \tag{3.28}$$

Class 2 $$\frac{\Delta\sigma_{pr}}{\sigma_{pi}} = 0,66 \; \rho_{1000} \; e^{9,1\,\mu} \left(\frac{t}{1000}\right)^{0,75\,(1-\mu)} 10^{-5} \tag{3.29}$$

Class 3 $$\frac{\Delta\sigma_{pr}}{\sigma_{pi}} = 1,98 \; \rho_{1000} \; e^{8\,\mu} \left(\frac{t}{1000}\right)^{0,75\,(1-\mu)} 10^{-5} \tag{3.30}$$

Where
   $\Delta\sigma_{pr}$ is absolute value of the relaxation losses of the prestress
   σ_{pi} For post-tensioning σ_{pi} is the absolute value of the initial prestress σ_{pi} = σ_{pm0} (see also 5.10.3 (2));

For pre-tensioning σ_{pi} is the maximum tensile stress applied to the tendon minus the immediate losses occurred during the stressing process see 5.10.4 (1) (i)

t is the time after tensioning (in hours)

μ $= \sigma_{pi}/f_{pk}$, where f_{pk} is the characteristic value of the tensile strength of the prestressing steel

ρ_{1000} is the value of relaxation loss (in %), at 1000 hours after tensioning and at a mean temperature of 20°C.

Note: Where the relaxation losses are calculated for different time intervals (stages) and greater accuracy is required, reference should be made to Annex D.

(8) The long term (final) values of the relaxation losses may be estimated for a time t equal to 500 000 hours (i.e. around 57 years).

(9) Relaxation losses are very sensitive to the temperature of the steel. Where heat treatment is applied (e.g. by steam), 10.3.2.2 applies. Otherwise where this temperature is greater than 50°C the relaxation losses should be verified.

3.3.3 Strength

(1)P The 0,1% proof stress ($f_{p0,1k}$) and the specified value of the tensile strength (f_{pk}) are defined as the characteristic value of the 0,1% proof load and the characteristic maximum load in axial tension respectively, divided by the nominal cross sectional area as shown in Figure 3.9.
Figure 3.9: Stress-strain diagram for typical prestressing steel (absolute values are shown for tensile stress and strain)

3.3.4 Ductility characteristics

(1)P The prestressing tendons shall have adequate ductility, as specified in EN 10138.

(2) Adequate ductility in elongation may be assumed if the prestressing tendons obtain the specified value of the elongation at maximum load given in EN 10138.

(3) Adequate ductility in bending may be assumed if the prestressing tendons satisfy the

requirements for bendability of EN ISO 15630.

(4) Stress-strain diagrams for the prestressing tendons, based on production data, shall be prepared and made available by the producer as an annex to the certificate accompanying the consignment (see 3.3.1 (9)P).

(5) Adequate ductility in tension may be assumed for the prestressing tendons if $f_{pk}/f_{p0,1k} \geq k$.

> **Note**: The value of k for use in a Country may be found in its National Annex. The recommended value is 1,1.

3.3.5 Fatigue

(1)P Prestressing tendons shall have adequate fatigue strength.

(2)P The fatigue stress range for prestressing tendons shall be in accordance with EN 10138 or given in an appropriate European Technical Approval.

3.3.6   Design assumptions

(1)P Structural analysis is performed on the basis of the nominal cross-section area of the prestressing steel and the characteristic values $f_{p0,1k}$, f_{pk} and ε_{uk}.

(2) The design value for the modulus of elasticity, E_p may be assumed equal to 205 GPa for wires and bars. The actual value can range from 195 to 210 GPa, depending on the manufacturing process. Certificates accompanying the consignment should give the appropriate value.

(3) The design value for the modulus of elasticity, E_p may be assumed equal to 195 GPa for strand. The actual value can range from 185 GPa to 205 GPa, depending on the manufacturing process. Certificates accompanying the consignment should give the appropriate value.

(4) The mean density of prestressing tendons for the purposes of design may normally be taken as 7850 kg/m^3

(5) The values given above may be assumed to be valid within a temperature range between -40°C and +100°C for the prestressing steel in the finished structure.

(6) The design value for the steel stress, f_{pd}, is taken as $f_{p0,1k}/\gamma_S$ (see Figure 3.10).

(7)   For cross-section design, either of the following assumptions may be made (see Figure 3.10):
- an inclined branch, with a strain limit ε_{ud}. The design may also be based on the actual stress/strain relationship, if this is known, with stress above the elastic limit reduced analogously with Figure 3.10, or

- a horizontal top branch without strain limit.

> **Note**: The value of ε_{ud} for use in a Country may be found in its National Annex. The recommended value is $0,9\varepsilon_{uk}$. If more accurate values are not known the recommended values are $\varepsilon_{ud} = 0,02$ and $f_{p0,1k}/f_{pk} = 0,9$.
Figure 3.10: Idealised and design stress-strain diagrams for prestressing steel (absolute values are shown for tensile stress and strain)

3.3.7 Prestressing tendons in sheaths

(1)P Prestressing tendons in sheaths (e.g. bonded tendons in ducts, unbonded tendons etc.) shall be adequately and permanently protected against corrosion (see 4.3).

(2)P Prestressing tendons in sheaths shall be adequately protected against the effects of fire (see EN 1992-1-2).

3.4 Prestressing devices

3.4.1 Anchorages and couplers

3.4.1.1 General

(1)P 3.4.1 applies to anchoring devices (anchorages) and coupling devices (couplers) for application in post-tensioned construction, where:
  (i) anchorages are used to transmit the forces in tendons to the concrete in the anchorage zone
  (ii) couplers are used to connect individual lengths of tendon to make continuous tendons.

(2)P Anchorages and couplers for the prestressing system considered shall be in accordance with the relevant European Technical Approval.

(3)P Detailing of anchorage zones shall be in accordance with 5.10, 8.10.3 and 8.10.4.

3.4.1.2 Mechanical properties

3.4.1.2.1 Anchored tendons

(1)P Prestressing tendon anchorage assemblies and prestressing tendon coupler assemblies shall have strength, elongation and fatigue characteristics sufficient to meet the requirements of the design.

(2) This may be assumed provided that:
- (i) The geometry and material characteristics of the anchorage and coupler components are in accordance with the appropriate European Technical Approval and that their premature failure is precluded.
- (ii) Failure of the tendon is not induced by the connection to the anchorage or coupler.
- (iii) The elongation at failure of the assemblies $\geq$ 2%.
- (iv) Tendon-anchorage assemblies are not located in otherwise highly-stressed zones.
- (v) Fatigue characteristics of the anchorage and coupler components are in accordance with the appropriate European Technical Approval.

3.4.1.2.2 Anchorage devices and anchorage zones

(1)P The strength of the anchorage devices and zones shall be sufficient for the transfer of the tendon force to the concrete and the formation of cracks in the anchorage zone shall not impair the function of the anchorage.

3.4.2 External non-bonded tendons

3.4.2.1 General

(1)P An external non-bonded tendon is a tendon situated outside the original concrete section and is connected to the structure by anchorages and deviators only.

(2)P The post-tensioning system for the use with external tendons shall be in accordance with the appropriate European Technical Approval.

(3) Reinforcement detailing should follow the rules given in 8.10.

3.4.2.2 Anchorages

(1) The minimum radius of curvature of the tendon in the anchorage zone for non- bonded tendons should be given in the appropriate European Technical Approval.

SECTION 4   DURABILITY AND COVER TO REINFORCEMENT

4.1   General

(1)P A durable structure shall meet the requirements of serviceability, strength and stability throughout its design working life, without significant loss of utility or excessive unforeseen maintenance (for general requirements see also EN 1990).

(2)P The required protection of the structure shall be established by considering its intended use, design working life (see EN 1990), maintenance programme and actions.

(3)P The possible significance of direct and indirect actions, environmental conditions (4.2) and consequential effects shall be considered.

> **Note:** Examples include deformations due to creep and shrinkage (see 2.3.2).

(4) Corrosion protection of steel reinforcement depends on density, quality and thickness of concrete cover (see 4.4) and cracking (see 7.3). The cover density and quality is achieved by controlling the maximum water/cement ratio and minimum cement content (see EN 206-1) and may be related to a minimum strength class of concrete.

> **Note:** Further information is given in Annex E.

(5) Where metal fastenings are inspectable and replaceable, they may be used with protective coatings in exposed situations.   Otherwise, they should be of corrosion resistant material.

(6) Further requirements to those given in this Section should be considered for special situations (e.g. for structures of temporary or monumental nature, structures subjected to extreme or unusual actions etc.).

4.2   Environmental conditions

(1)P Exposure conditions are chemical and physical conditions to which the structure is exposed in addition to the mechanical actions.

(2)   Environmental conditions are classified according to Table 4.1, based on EN 206-1.

(3) In addition to the conditions in Table 4.1, particular forms of aggressive or indirect action should be considered including:
   chemical attack, arising from e.g.
   - the use of the building or the structure (storage of liquids, etc)
   - solutions of acids or sulfate salts (EN 206-1, ISO 9690)
   - chlorides contained in the concrete (EN 206-1)
   - alkali-aggregate reactions (EN 206-1, National Standards)

   physical attack, arising from e.g.
   - temperature change
   - abrasion (see 4.4.1.2 (13))
   - water penetration (EN 206-1).

Table 4.1: Exposure classes related to environmental conditions in accordance with EN 206-1

Class designation	Description of the environment	Informative examples where exposure classes may occur
1 No risk of corrosion or attack		
X0	For concrete without reinforcement or embedded metal: all exposures except where there is freeze/thaw, abrasion or chemical attack For concrete with reinforcement or embedded metal: very dry	Concrete inside buildings with very low air humidity
2 Corrosion induced by carbonation		
XC1	Dry or permanently wet	Concrete inside buildings with low air humidity Concrete permanently submerged in water
XC2	Wet, rarely dry	Concrete surfaces subject to long-term water contact Many foundations
XC3	Moderate humidity	Concrete inside buildings with moderate or high air humidity External concrete sheltered from rain
XC4	Cyclic wet and dry	Concrete surfaces subject to water contact, not within exposure class XC2
3 Corrosion induced by chlorides		
XD1	Moderate humidity	Concrete surfaces exposed to airborne chlorides
XD2	Wet, rarely dry	Swimming pools Concrete components exposed to industrial waters containing chlorides
XD3	Cyclic wet and dry	Parts of bridges exposed to spray containing chlorides Pavements Car park slabs
4 Corrosion induced by chlorides from sea water		
XS1	Exposed to airborne salt but not in direct contact with sea water	Structures near to or on the coast
XS2	Permanently submerged	Parts of marine structures
XS3	Tidal, splash and spray zones	Parts of marine structures
5. Freeze/Thaw Attack		
XF1	Moderate water saturation, without de-icing agent	Vertical concrete surfaces exposed to rain and freezing
XF2	Moderate water saturation, with de-icing agent	Vertical concrete surfaces of road structures exposed to freezing and airborne de-icing agents
XF3	High water saturation, without de-icing agents	Horizontal concrete surfaces exposed to rain and freezing
XF4	High water saturation with de-icing agents or sea water	Road and bridge decks exposed to de-icing agents Concrete surfaces exposed to direct spray containing de-icing agents and freezing Splash zone of marine structures exposed to freezing
6. Chemical attack		
XA1	Slightly aggressive chemical environment according to EN 206-1, Table 2	Natural soils and ground water
XA2	Moderately aggressive chemical environment according to EN 206-1, Table 2	Natural soils and ground water
XA3	Highly aggressive chemical environment according to EN 206-1, Table 2	Natural soils and ground water

Note: The composition of the concrete affects both the protection of the reinforcement and the resistance of the concrete to attack. Annex E gives indicative strength classes for the particular environmental exposure classes. This may lead to the choice of higher strength classes than required for the structural design. In such cases the value of f_{ctm} should be associated with the higher strength in the calculation of minimum reinforcement and crack width control (see 7.3.2 -7.3.4).

4.3 Requirements for durability

(1)P In order to achieve the required design working life of the structure, adequate measures shall be taken to protect each structural element against the relevant environmental actions.

(2)P The requirements for durability shall be included when considering the following:
Structural conception,
Material selection,
Construction details,
Execution,
Quality Control,
Inspection,
Verifications,
Special measures (e.g. use of stainless steel, coatings, cathodic protection).

4.4 Methods of verification

4.4.1 Concrete cover

4.4.1.1 General

(1)P The concrete cover is the distance between the surface of the reinforcement closest to the nearest concrete surface (including links and stirrups and surface reinforcement where relevant) and the nearest concrete surface.

(2)P The nominal cover shall be specified on the drawings. It is defined as a minimum cover, c_{min} (see 4.4.1.2), plus an allowance in design for deviation, Δc_{dev} (see 4.4.1.3):

$$c_{nom} = c_{min} + \Delta c_{dev}$$ (4.1)

4.4.1.2 Minimum cover, c_{min}

(1)P Minimum concrete cover, c_{min}, shall be provided in order to ensure:
- the safe transmission of bond forces (see also Sections 7 and 8)
- the protection of the steel against corrosion (durability)
- an adequate fire resistance (see EN 1992-1-2)

(2)P The greater value for c_{min} satisfying the requirements for both bond and environmental conditions shall be used.

$$c_{min} = \max \{c_{min,b}; c_{min,dur} + \Delta c_{dur,\gamma} - \Delta c_{dur,st} - \Delta c_{dur,add}; 10 \text{ mm}\}$$ (4.2)

where:
$c_{min,b}$ minimum cover due to bond requirement, see 4.4.1.2 (3)
$c_{min,dur}$ minimum cover due to environmental conditions, see 4.4.1.2 (5)
$\Delta c_{dur,\gamma}$ additive safety element, see 4.4.1.2 (6)
$\Delta c_{dur,st}$ reduction of minimum cover for use of stainless steel, see 4.4.1.2 (7)
$\Delta c_{dur,add}$ reduction of minimum cover for use of additional protection, see 4.4.1.2 (8)

(3) In order to transmit bond forces safely and to ensure adequate compaction of the concrete, the minimum cover should not be less than $c_{min,b}$ given in table 4.2.

Table 4.2: Minimum cover, $c_{min,b}$, requirements with regard to bond

Bond Requirement	
Arrangement of bars	Minimum cover $c_{min,b}$*
Separated	Diameter of bar
Bundled	Equivalent diameter (ϕ_n)(see 8.9.1)
*: If the nominal maximum aggregate size is greater than 32 mm, $c_{min,b}$ should be increased by 5 mm.	

Note: The values of $c_{min,b}$ for post-tensioned circular and rectangular ducts for bonded tendons, and pre-tensioned tendons for use in a Country may be found in its National Annex. The recommended values for post-tensioned ducts are:
    circular ducts: diameter
    rectangular ducts: greater of the smaller dimension or half the greater dimension
There is no requirement for more than 80 mm for either circular or rectangular ducts.

The recommended values for pre-tensioned tendon:
    1,5 x diameter of strand or plain wire
    2,5 x diameter of indented wire.

(4) For prestressing tendons, the minimum cover of the anchorage should be provided in accordance with the appropriate European Technical Approval.

(5) The minimum cover values for reinforcement and prestressing tendons in normal weight concrete taking account of the exposure classes and the structural classes is given by $c_{min,dur}$.

Note: Structural classification and values of $c_{min,dur}$ for use in a Country may be found in its National Annex. The recommended Structural Class (design working life of 50 years) is S4 for the indicative concrete strengths given in Annex E and the recommended modifications to the structural class is given in Table 4.3N. The recommended minimum Structural Class is S1.

The recommended values of $c_{min,dur}$ are given in Table 4.4N (reinforcing steel) and Table 4.5N (prestressing steel).

Table 4.3N: Recommended structural classification

Structural Class							
Criterion	Exposure Class according to Table 4.1						
	X0	XC1	XC2 / XC3	XC4	XD1	XD2 / XS1	XD3 / XS2 / XS3
Design Working Life of 100 years	increase class by 2	increase class by 2	increase class by 2	increase class by 2	increase class by 2	increase class by 2	increase class by 2
Strength Class [1) 2)]	≥ C30/37 reduce class by 1	≥ C30/37 reduce class by 1	≥ C35/45 reduce class by 1	≥ C40/50 reduce class by 1	≥ C40/50 reduce class by 1	≥ C40/50 reduce class by 1	≥ C45/55 reduce class by 1
Member with slab geometry (position of reinforcement not affected by construction process)	reduce class by 1	reduce class by 1	reduce class by 1	reduce class by 1	reduce class by 1	reduce class by 1	reduce class by 1
Special Quality Control of the concrete production ensured	reduce class by 1	reduce class by 1	reduce class by 1	reduce class by 1	reduce class by 1	reduce class by 1	reduce class by 1

Notes to Table 4.3N
1. The strength class and w/c ratio are considered to be related values. A special composition (type of cement, w/c value, fine fillers) with the intent to produce low permeability may be considered.
2. The limit may be reduced by one strength class if air entrainment of more than 4% is applied.

Table 4.4N: Values of minimum cover, $c_{min,dur}$, requirements with regard to durability for reinforcement steel in accordance with EN 10080.

Environmental Requirement for $c_{min,dur}$ (mm)							
Structural Class	Exposure Class according to Table 4.1						
	X0	XC1	XC2 / XC3	XC4	XD1 / XS1	XD2 / XS2	XD3 / XS3
S1	10	10	10	15	20	25	30
S2	10	10	15	20	25	30	35
S3	10	10	20	25	30	35	40
S4	10	15	25	30	35	40	45
S5	15	20	30	35	40	45	50
S6	20	25	35	40	45	50	55

Table 4.5N: Values of minimum cover, $c_{min,dur}$, requirements with regard to durability for prestressing steel

Environmental Requirement for $c_{min,dur}$ (mm)							
Structural Class	Exposure Class according to Table 4.1						
	X0	XC1	XC2 / XC3	XC4	XD1 / XS1	XD2 / XS2	XD3 / XS3
S1	10	15	20	25	30	35	40
S2	10	15	25	30	35	40	45
S3	10	20	30	35	40	45	50
S4	10	25	35	40	45	50	55
S5	15	30	40	45	50	55	60
S6	20	35	45	50	55	60	65

(6) The concrete cover should be increased by the additive safety element $\Delta c_{dur,\gamma}$.

Note: The value of $\Delta c_{dur,\gamma}$ for use in a Country may be found in its National Annex. The recommended value is 0 mm.

(7) Where stainless steel is used or where other special measures have been taken, the minimum cover may be reduced by $\Delta c_{dur,st}$. For such situations the effects on all relevant material properties should be considered, including bond.

Note: The value of $\Delta c_{dur,st}$ for use in a Country may be found in its National Annex. The recommended value, without further specification, is 0 mm.

(8) For concrete with additional protection (e.g. coating) the minimum cover may be reduced by $\Delta c_{dur,add}$.

Note: The value of $\Delta c_{dur,add}$ for use in a Country may be found in its National Annex. The recommended value, without further specification, is 0 mm.

(9) Where in-situ concrete is placed against other concrete elements (precast or in-situ) the minimum concrete cover of the reinforcement to the interface may be reduced to a value corresponding to the requirement for bond (see (3) above) provided that:
  - the strength class of concrete is at least C25/30,
  - the exposure time of the concrete surface to an outdoor environment is short (< 28 days),
  - the interface has been roughened.

(10) For unbonded tendons the cover should be provided in accordance with the European Technical Approval.

(11) For uneven surfaces (e.g. exposed aggregate) the minimum cover should be increased by at least 5 mm.

(12) Where freeze/thaw or chemical attack on concrete (Classes XF and XA) is expected special attention should be given to the concrete composition (see EN 206-1 Section 6). Cover in accordance with 4.4 will normally be sufficient for such situations.

(13) For concrete abrasion special attention should be given on the aggregate according to EN 206-1. Optionally concrete abrasion may be allowed for by increasing the concrete cover (sacrificial layer). In that case the minimum cover c_{min} should be increased by k_1 for Abrasion Class XM1, by k_2 for XM2 and by k_3 for XM3.

> **Note:** Abrasion Class XM1 means a moderate abrasion like for members of industrial sites frequented by vehicles with air tyres. Abrasion Class XM2 means a heavy abrasion like for members of industrial sites frequented by fork lifts with air or solid rubber tyres. Abrasion Class XM3 means an extreme abrasion like for members industrial sites frequented by fork lifts with elastomer or steel tyres or track vehicles.
> The values of k_1, k_2 and k_3 for use in a Country may be found in its National Annex. The recommended values are 5 mm, 10 mm and 15 mm.

4.4.1.3 Allowance in design for deviation

(1)P To calculate the nominal cover, c_{nom}, an addition to the minimum cover shall be made in design to allow for the deviation (Δc_{dev}). The required minimum cover shall be increased by the absolute value of the accepted negative deviation.

> **Note:** The value of Δc_{dev} for use in a Country may be found in its National Annex. The recommended value is 10 mm.

(2) For Buildings, ENV 13670-1 gives the acceptable deviation. This is normally also sufficient for other types of structures. It should be considered when choosing the value of nominal cover for design. The nominal value of cover for design should be used in the calculations and stated on the drawings, unless a value other than the nominal cover is specified (e.g. minimum value).

(3) In certain situations, the accepted deviation and hence allowance, Δc_{dev}, may be reduced.

> **Note:** The reduction in Δc_{dev} in such circumstances for use in a Country may be found in its National Annex. The recommended values are:
> - where fabrication is subjected to a quality assurance system, in which the monitoring includes measurements of the concrete cover, the allowance in design for deviation Δc_{dev} may be reduced:
>
> $$10 \text{ mm} \geq \Delta c_{dev} \geq 5 \text{ mm} \tag{4.3N}$$
> - where it can be assured that a very accurate measurement device is used for monitoring and non conforming members are rejected (e.g. precast elements), the allowance in design for deviation Δc_{dev} may be reduced:
>
> $$10 \text{ mm} \geq \Delta c_{dev} \geq 0 \text{ mm} \tag{4.4N}$$

(4) For concrete cast against uneven surfaces, the minimum cover should generally be increased by allowing larger deviations in design. The increase should comply with the difference caused by the unevenness, but the minimum cover should be at least k_1 mm for concrete cast against prepared ground (including blinding) and k_2 mm for concrete cast directly against soil. The cover to the reinforcement for any surface feature, such as ribbed finishes or exposed aggregate, should also be increased to take account of the uneven surface (see 4.4.1.2 (11)).

> **Note:** The values of k_1 and k_2 for use in a Country may be found in its National Annex. The recommended values are 40 mm and 75 mm.

SECTION 5 STRUCTURAL ANALYSIS

5.1 General

5.1.1 General requirements

(1)P The purpose of structural analysis is to establish the distribution of either internal forces and moments, or stresses, strains and displacements, over the whole or part of a structure. Additional local analysis shall be carried out where necessary.

> **Note:** In most normal cases analysis will be used to establish the distribution of internal forces and moments, and the complete verification or demonstration of resistance of cross sections is based on these action effects; however, for certain particular elements, the methods of analysis used (e.g. finite element analysis) give stresses, strains and displacements rather than internal forces and moments. Special methods are required to use these results to obtain appropriate verification.

(2) Local analyses may be necessary where the assumption of linear strain distribution is not valid, e.g.:
- in the vicinity of supports
- local to concentrated loads
- in beam-column intersections
- in anchorage zones
- at changes in cross section.

(3) For in-plane stress fields a simplified method for determining reinforcement may be used.

> **Note:** A simplified method is given in Annex F.

(4)P Analyses shall be carried out using idealisations of both the geometry and the behaviour of the structure. The idealisations selected shall be appropriate to the problem being considered.

(5) The geometry and the properties of the structure and its behaviour at each stage of construction shall be considered in the design.

(6)P The effect of the geometry and properties of the structure on its behaviour at each stage of construction shall be considered in the design

(7) Common idealisations of the behaviour used for analysis are:
- linear elastic behaviour (see 5.4)
- linear elastic behaviour with limited redistribution (see 5.5)
- plastic behaviour (see 5.6), including strut and tie models (see 5.6.4)
- non-linear behaviour (see 5.7)

(8) In buildings, the effects of shear and axial forces on the deformations of linear elements and slabs may be ignored where these are likely to be less than 10% of those due to bending.

5.1.2 Special requirements for foundations

(1)P Where ground-structure interaction has significant influence on the action effects in the structure, the properties of the soil and the effects of the interaction shall be taken into account in accordance with EN 1997-1.

> **Note:** For more information concerning the analysis of shallow foundations see Annex G.

(2) For the design of spread foundations, appropriately simplified models for the description of the soil-structure interaction may be used.

> **Note:** For simple pad footings and pile caps the effects of soil-structure interaction may usually be ignored.

(3) For the strength design of individual piles the actions should be determined taking into account the interaction between the piles, the pile cap and the supporting soil.

(4) Where the piles are located in several rows, the action on each pile should be evaluated by considering the interaction between the piles.

(5) This interaction may be ignored when the clear distance between the piles is greater than two times the pile diameter.

5.1.3 Load cases and combinations

(1)P In considering the combinations of actions, see EN 1990 Section 6, the relevant cases shall be considered to enable the critical design conditions to be established at all sections, within the structure or part of the structure considered.

> **Note:** Where a simplification in the number of load arrangements for use in a Country is required, reference is made to its National Annex. The following simplified load arrangements are recommended for buildings:
>
> (a) alternate spans carrying the design variable and permanent load ($\gamma_Q Q_k + \gamma_G G_k + P_m$), other spans carrying only the design permanent load, $\gamma_G G_k + P_m$ and
>
> (b) any two adjacent spans carrying the design variable and permanent loads ($\gamma_Q Q_k + \gamma_G G_k + P_m$). All other spans carrying only the design permanent load, $\gamma_G G_k + P_m$.

5.1.4 Second order effects

(1)P Second order effects (see EN 1990 Section 1) shall be taken into account where they are likely to affect the overall stability of a structure significantly and for the attainment of the ultimate limit state at critical sections.

(2) Second order effects should be taken into account according to 5.8.

(3) For buildings, second order effects below certain limits may be ignored (see 5.8.2 (6)).

5.2 Geometric imperfections

(1)P The unfavourable effects of possible deviations in the geometry of the structure and the position of loads shall be taken into account in the analysis of members and structures.

> **Note:** Deviations in cross section dimensions are normally taken into account in the material safety factors. These should not be included in structural analysis. A minimum eccentricity for cross section design is given in 6.1 (4).

(2)P Imperfections shall be taken into account in ultimate limit states in persistent and accidental design situations.

(3) Imperfections need not be considered for serviceability limit states.

(4) The following provisions apply for members with axial compression and structures with vertical load, mainly in buildings. Numerical values are related to normal execution deviations

(Class 1 in ENV 13670). With the use of other deviations (e.g. Class 2), values should be adjusted accordingly.

(5) Imperfections may be represented by an inclination, θ_i, given by:

$$\theta_i = \theta_0 \cdot \alpha_h \cdot \alpha_m \tag{5.1}$$

where

θ_0 is the basic value:

α_h is the reduction factor for length or height: $\alpha_h = 2/\sqrt{l} \; ; \; 2/3 \le \alpha_h \le 1$

α_m is the reduction factor for number of members: $\alpha_m = \sqrt{0{,}5(1+1/m)}$

l is the length or height [m], see (4)

m is the number of vertical members contributing to the total effect

Note: The value of θ_0 for use in a Country may be found in its National Annex. The recommended value is 1/200

(6) In Expression (5.1), the definition of l and m depends on the effect considered, for which three main cases can be distinguished (see also Figure 5.1):

- Effect on isolated member: l = actual length of member, m =1.

- Effect on bracing system: l = height of building, m = number of vertical members contributing to the horizontal force on the bracing system.

- Effect on floor or roof diaphragms distributing the horizontal loads: l = storey height, m = number of vertical elements in the storey(s) contributing to the total horizontal force on the floor.

(7) For isolated members (see 5.8.1), the effect of imperfections may be taken into account in two alternative ways a) or b):

a) as an eccentricity, e_i, given by

$$e_i = \theta_i \, l_0 / 2 \tag{5.2}$$

where l_0 is the effective length, see 5.8.3.2

For walls and isolated columns in braced systems, $e_i = l_0/400$ may always be used as a simplification, corresponding to $\alpha_h = 1$.

b) as a transverse force, H_i, in the position that gives maximum moment:

for unbraced members (see Figure 5.1 a1):
$$H_i = \theta_i N \tag{5.3a}$$

for braced members (see Figure 5.1 a2):
$$H_i = 2\theta_i N \tag{5.3b}$$

where N is the axial load

Note: Eccentricity is suitable for statically determinate members, whereas transverse load can be used for both determinate and indeterminate members. The force H_i may be substituted by some other equivalent transverse action.

a1) Unbraced　　　　　　　　　　　**a2) Braced**

a) Isolated members with eccentric axial force or lateral force

b) Bracing system　　　**c1) Floor diaphragm**　　**c2) Roof diaphragm**
Figure 5.1: Examples of the effect of geometric imperfections

(8) For structures, the effect of the inclination θ_i may be represented by transverse forces, to be included in the analysis together with other actions.

Effect on bracing system, (see Figure 5.1 b):

$$H_i = \theta_i \, (N_b - N_a) \tag{5.4}$$

Effect on floor diaphragm, (see Figure 5.1 c1):

$$H_i = \theta_i (N_b + N_a) \, / \, 2 \tag{5.5}$$

Effect on roof diaphragm, (see Figure 5.1 c2):

$$H_i = \theta_i \cdot N_a \tag{5.6}$$

where N_a and N_b are longitudinal forces contributing to H_i.

(9) As a simplified alternative for walls and isolated columns in braced systems, an eccentricity $e_i = l_0/400$ may be used to cover imperfections related to normal execution deviations (see 5.2(4)).

5.3   Idealisation of the structure

5.3.1   Structural models for overall analysis

(1)P The elements of a structure are classified, by consideration of their nature and function, as beams, columns, slabs, walls, plates, arches, shells etc. Rules are provided for the analysis of the commoner of these elements and of structures consisting of combinations of these elements.

(2) For buildings the following provisions (3) to (7) are applicable:

(3) A beam is a member for which the span is not less than 3 times the overall section depth. Otherwise it should be considered as a deep beam.

(4) A slab is a member for which the minimum panel dimension is not less than 5 times the overall slab thickness.

(5) A slab subjected to dominantly uniformly distributed loads may be considered to be one-way spanning if either:
    - it possesses two free (unsupported) and sensibly parallel edges, or
    - it is the central part of a sensibly rectangular slab supported on four edges with a ratio of the longer to shorter span greater than 2.

(6) Ribbed or waffle slabs need not be treated as discrete elements for the purposes of analysis, provided that the flange or structural topping and transverse ribs have sufficient torsional stiffness. This may be assumed provided that:
    - the rib spacing does not exceed 1500 mm
    - the depth of the rib below the flange does not exceed 4 times its width.
    - the depth of the flange is at least 1/10 of the clear distance between ribs or 50 mm, whichever is the greater.
    - transverse ribs are provided at a clear spacing not exceeding 10 times the overall depth of the slab.

The minimum flange thickness of 50 mm may be reduced to 40 mm where permanent blocks are incorporated between the ribs.

(7) A column is a member for which the section depth does not exceed 4 times its width and the height is at least 3 times the section depth. Otherwise it should be considered as a wall.

5.3.2 Geometric data

5.3.2.1 Effective width of flanges (all limit states)

(1)P In T beams the effective flange width, over which uniform conditions of stress can be assumed, depends on the web and flange dimensions, the type of loading, the span, the support conditions and the transverse reinforcement.

(2) The effective width of flange should be based on the distance l_0 between points of zero moment, which may be obtained from Figure 5.2.
Figure 5.2: Definition of l_0, for calculation of effective flange width

Note: The length of the cantilever, l_3, should be less than half the adjacent span and the ratio of adjacent spans should lie between 2/3 and 1,5.

(3) The effective flange width b_{eff} for a T beam or *L* beam may be derived as:

$$b_{eff} = \sum b_{eff,i} + b_w \leq b \qquad (5.7)$$

where
$$b_{eff,i} = 0,2b_i + 0,1l_0 \leq 0,2l_0 \qquad (5.7a)$$
and
$$b_{eff,i} \leq b_i \qquad (5.7b)$$

(for the notations see Figures 5.2 above and 5.3 below).
Figure 5.3: Effective flange width parameters

(4) For structural analysis, where a great accuracy is not required, a constant width may be assumed over the whole span. The value applicable to the span section should be adopted.

5.3.2.2 Effective span of beams and slabs in buildings

Note: The following provisions are provided mainly for member analysis. For frame analysis some of these simplifications may be used where appropriate.

(1) The effective span, l_{eff}, of a member should be calculated as follows:

$$l_{eff} = l_n + a_1 + a_2 \qquad (5.8)$$

where:
    l_n is the clear distance between the faces of the supports;
    values for a_1 and a_2, at each end of the span, may be determined from the appropriate a_i values in Figure 5.4 where t is the width of the supporting element as shown.

$a_i = \min\{1/2h; 1/2t\}$

(e) Cantilever
Figure 5.4: Effective span (l_{eff}) for different support conditions

(2) Continuous slabs and beams may generally be analysed on the assumption that the supports provide no rotational restraint.

(3) Where a beam or slab is monolithic with its supports, the critical design moment at the support should be taken as that at the face of the support. The design moment and reaction transferred to the supporting element (e.g. column, wall, etc.) should be generally taken as the greater of the elastic or redistributed values.

Note: The moment at the face of the support should not be less than 0,65 that of the full fixed end moment.

(4) Regardless of the method of analysis used, where a beam or slab is continuous over a support which may be considered to provide no restraint to rotation (e.g. over walls), the design support moment, calculated on the basis of a span equal to the centre-to-centre distance between supports, may be reduced by an amount ΔM_{Ed} as follows:

$$\Delta M_{Ed} = F_{Ed,sup}\, t\, /\, 8 \tag{5.9}$$

where:

   $F_{Ed,sup}$ is the design support reaction
   t is the breadth of the support (see Figure 5.4 b))

Note: Where support bearings are used t should be taken as the bearing width.

5.4   Linear elastic analysis

(1) Linear analysis of elements based on the theory of elasticity may be used for both the serviceability and ultimate limit states.

(2) For the determination of the action effects, linear analysis may be carried out assuming:
   i) uncracked cross sections,
   ii) linear stress-strain relationships and
   iii) mean value of the modulus of elasticity.

(3) For thermal deformation, settlement and shrinkage effects at the ultimate limit state (ULS), a reduced stiffness corresponding to the cracked sections, neglecting tension stiffening but including the effects of creep, may be assumed. For the serviceability limit state (SLS) a gradual evolution of cracking should be considered.

5.5   Linear elastic analysis with limited redistribution

(1)P The influence of any redistribution of the moments on all aspects of the design shall be considered.

(2) Linear analysis with limited redistribution may be applied to the analysis of structural members for the verification of ULS.

(3) The moments at ULS calculated using a linear elastic analysis may be redistributed, provided that the resulting distribution of moments remains in equilibrium with the applied loads.

(4) In continuous beams or slabs which:
   a) are predominantly subject to flexure and
   b) have the ratio of the lengths of adjacent spans in the range of 0,5 to 2,
redistribution of bending moments may be carried out without explicit check on the rotation capacity, provided that:

$$\delta \geq k_1 + k_2 x_u/d \quad \text{for } f_{ck} \leq 50 \text{ MPa} \tag{5.10a}$$

$$\delta \geq k_3 + k_4 x_u/d \quad \text{for } f_{ck} > 50 \text{ MPa} \tag{5.10b}$$

   $\geq k_5$ where Class B and Class C reinforcement is used (see Annex C)
   $\geq k_6$ where Class A reinforcement is used (see Annex C)

Where:

   δ is the ratio of the redistributed moment to the elastic bending moment
   x_u is the depth of the neutral axis at the ultimate limit state after redistribution

d   is the effective depth of the section

Note: The values of k_1, k_2, k_3, k_4, k_5 and k_6 for use in a Country may be found in its National Annex. The recommended value for k_1 is 0,44, for k_2 is 1,25(0,6+0,0014/ε_{cu2}), for k_3 = 0,54, for k_4 = 1,25(0,6+0,0014/ε_{cu2}), for k_5 = 0,7 and k_6 = 0,8. ε_{cu2} is the ultimate strain according to Table 3.1.

(5) Redistribution should not be carried out in circumstances where the rotation capacity cannot be defined with confidence (e.g. in the corners of prestressed frames).

(6) For the design of columns the elastic moments from frame action should be used without any redistribution.

5.6   Plastic analysis

5.6.1   General

(1)P Methods based on plastic analysis shall only be used for the check at ULS.

(2)P The ductility of the critical sections shall be sufficient for the envisaged mechanism to be formed.

(3)P The plastic analysis should be based either on the lower bound (static) method or on the upper bound (kinematic) method.

Note: A Country's National Annex Guidance may refer to non-contradictory complementary information.

(4) The effects of previous applications of loading may generally be ignored, and a monotonic increase of the intensity of actions may be assumed.

5.6.2 Plastic analysis for beams, frames and slabs

(1)P Plastic analysis without any direct check of rotation capacity may be used for the ultimate limit state if the conditions of 5.6.1 (2)P are met.

(2) The required ductility may be deemed to be satisfied without explicit verification if all the following are fulfilled:
   i) the area of tensile reinforcement is limited such that, at any section
      $x_u/d \leq 0,25$ for concrete strength classes $\leq$ C50/60
      $x_u/d \leq 0,15$ for concrete strength classes $\geq$ C55/67
  ii) reinforcing steel is either Class B or C
 iii)   the ratio of the moments at intermediate supports to the moments in the span should be between 0,5 and 2.

(3) Columns should be checked for the maximum plastic moments which can be transmitted by connecting members. For connections to flat slabs this moment should be included in the punching shear calculation.

(4) When plastic analysis of slabs is carried out account should be taken of any non-uniform reinforcement, corner tie down forces, and torsion at free edges.

(5) Plastic methods may be extended to non-solid slabs (ribbed, hollow, waffle slabs) if their response is similar to that of a solid slab, particularly with regard to the torsional effects.

5.6.3 Rotation capacity

(1) The simplified procedure for continuous beams and continuous one way spanning slabs is based on the rotation capacity of beam/slab zones over a length of approximately 1,2 times the depth of section. It is assumed that these zones undergo a plastic deformation (formation of yield hinges) under the relevant combination of actions. The verification of the plastic rotation in the ultimate limit state is considered to be fulfilled, if it is shown that under the relevant combination of actions the calculated rotation, θ_s, is less than or equal to the allowable plastic rotation (see Figure 5.5).
Figure 5.5: Plastic rotation θ_s of reinforced concrete sections for continuous beams and continuous one way spanning slabs.

(2) In regions of yield hinges, x_u/d shall not exceed the value 0,45 for concrete strength classes less than or equal to C50/60, and 0,35 for concrete strength classes greater than or equal to C55/67.

(3) The rotation θ_s should be determined on the basis of the design values for actions and materials and on the basis of mean values for prestressing at the relevant time.

(4) In the simplified procedure, the allowable plastic rotation may be determined by multiplying the basic value of allowable rotation, $\theta_{pl,d}$, by a correction factor k_λ that depends on the shear slenderness.

Note: Values of $\theta_{pl,d}$ for use in a Country may be found in its National Annex. The recommended values for steel Classes B and C (the use of Class A steel is not recommended for plastic analysis) and concrete strength classes less than or equal to C50/60 and C90/105 are given in Figure 5.6N.

The values for concrete strength classes C 55/67 to C 90/105 may be interpolated accordingly. The values apply for a shear slenderness $\lambda = 3,0$. For different values of shear slenderness $\theta_{pl,d}$ should be multiplied by k_λ:

$$k_\lambda = \sqrt{\lambda/3} \qquad\qquad (5.11N)$$

Where λ is the ratio of the distance between point of zero and maximum moment after redistribution and effective depth, d.

As a simplification λ may be calculated for the concordant design values of the bending moment and shear :

$$\lambda = M_{Sd} / (V_{Sd} \cdot d) \qquad\qquad (5.12N)$$
Figure 5.6N: Basic value of allowable rotation, $\theta_{pl,d}$, of reinforced concrete sections for Class B and C reinforcement. The values apply for a shear slenderness $\lambda = 3,0$

5.6.4 Analysis with strut and tie models

(1) Strut and tie models may be used for design in ULS of continuity regions (cracked state of beams and slabs, see 6.1 - 6.4) and for the design in ULS and detailing of discontinuity regions (see 6.5). In general these extend up to a distance h (section depth of member) from the discontinuity. Strut and tie models may also be used for members where a linear distribution within the cross section is assumed, e.g. plane strain.

(2) Verifications in SLS may also be carried out using strut-and-tie models, e.g. verification of steel stresses and crack width control, if approximate compatibility for strut-and-tie models is ensured (in particular the position and direction of important struts should be oriented according to linear elasticity theory)

(3) Strut-and-tie models consist of struts representing compressive stress fields, of ties representing the reinforcement, and of the connecting nodes. The forces in the elements of a strut-and-tie model should be determined by maintaining the equilibrium with the applied loads in the ultimate limit state. The elements of strut-and-tie models should be dimensioned according to the rules given in 6.5.

(4) The ties of a strut-and-tie model should coincide in position and direction with the corresponding reinforcement.

(5) Possible means for developing suitable strut-and-tie models include the adoption of stress trajectories and distributions from linear-elastic theory or the load path method. All strut-and-tie models may be optimised by energy criteria.

5.7 Non-linear analysis

(1) Non-linear methods of analysis may be used for both ULS and SLS, provided that equilibrium and compatibility are satisfied and an adequate non-linear behaviour for materials is assumed. The analysis may be first or second order.

(2) At the ultimate limit state, the ability of local critical sections to withstand any inelastic deformations implied by the analysis should be checked, taking appropriate account of uncertainties.

(3) For structures predominantly subjected to static loads, the effects of previous applications of loading may generally be ignored, and a monotonic increase of the intensity of the actions may be assumed.

(4)P The use of material characteristics which represent the stiffness in a realistic way but take account of the uncertainties of failure shall be used when using non-linear analysis. Only those design formats which are valid within the relevant fields of application shall be used.

(5) For slender structures, in which second order effects cannot be ignored, the design method given in 5.8.6 may be used.

5.8   Analysis of second order effects with axial load

5.8.1 Definitions

Biaxial bending: simultaneous bending about two principal axes

Braced members or systems: structural members or subsystems, which in analysis and design are assumed *not* to contribute to the overall horizontal stability of a structure

Bracing members or systems: structural members or subsystems, which in analysis and design are assumed to contribute to the overall horizontal stability of a structure

Buckling: failure due to instability of a member or structure under perfectly axial compression and without transverse load

Note. "Pure buckling" as defined above is not a relevant limit state in real structures, due to imperfections and transverse loads, but a nominal buckling load can be used as a parameter in some methods for second order analysis.

Buckling load: the load at which buckling occurs; for isolated elastic members it is synonymous with the Euler load

Effective length: a length used to account for the shape of the deflection curve; it can also be defined as buckling length, i.e. the length of a pin-ended column with constant normal force, having the same cross section and buckling load as the actual member

First order effects: action effects calculated without consideration of the effect of structural deformations, but including geometric imperfections

Isolated members: members that *are* isolated, or members in a structure that for design purposes may be treated as being isolated; examples of isolated members with different boundary conditions are shown in Figure 5.7.

Nominal second order moment: a second order moment used in certain design methods, giving a total moment compatible with the ultimate cross section resistance (see 5.8.5 (2))

Second order effects: additional action effects caused by structural deformations

5.8.2 General

(1)P This clause deals with members and structures in which the structural behaviour is significantly influenced by second order effects (e.g. columns, walls, piles, arches and shells). Global second order effects are likely to occur in structures with a flexible bracing system.

(2)P Where second order effects are taken into account, see (6), equilibrium and resistance shall be verified in the deformed state. Deformations shall be calculated taking into account the relevant effects of cracking, non-linear material properties and creep.

> **Note**. In an analysis assuming linear material properties, this can be taken into account by means of reduced stiffness values, see 5.8.7.

(3)P Where relevant, analysis shall include the effect of flexibility of adjacent members and foundations (soil-structure interaction).

(4)P The structural behaviour shall be considered in the direction in which deformations can occur, and biaxial bending shall be taken into account when necessary.

(5)P Uncertainties in geometry and position of axial loads shall be taken into account as additional first order effects based on geometric imperfections, see 5.2.

(6) Second order effects may be ignored if they are less than 10 % of the corresponding first order effects. Simplified criteria are given for isolated members in 5.8.3.1 and for structures in 5.8.3.3.

5.8.3 Simplified criteria for second order effects

5.8.3.1 Slenderness criterion for isolated members

(1) As an alternative to 5.8.2 (6), second order effects may be ignored if the slenderness λ (as defined in 5.8.3.2) is below a certain value λ_{lim}.

> **Note:** The value of λ_{lim} for use in a Country may be found in its National Annex. The recommended value follows from:
>
> $$\lambda_{lim} = 20 \cdot A \cdot B \cdot C / \sqrt{n} \qquad\qquad (5.13N)$$
>
> where:
>
> | | | |
> |---|---|---|
> | A | = $1 / (1+0{,}2\varphi_{ef})$ | (if φ_{ef} is not known, $A = 0{,}7$ may be used) |
> | B | = $\sqrt{1 + 2\omega}$ | (if ω is not known, $B = 1{,}1$ may be used) |
> | C | = $1{,}7 - r_m$ | (if r_m is not known, $C = 0{,}7$ may be used) |
>
> φ_{ef} effective creep ratio; see 5.8.4;
> ω = $A_s f_{yd} / (A_c f_{cd})$; mechanical reinforcement ratio;
> A_s is the total area of longitudinal reinforcement
> n = $N_{Ed} / (A_c f_{cd})$; relative normal force
> r_m = M_{01}/M_{02}; moment ratio
> M_{01}, M_{02} are the first order end moments, $|M_{02}| \geq |M_{01}|$

If the end moments M_{01} and M_{02} give tension on the same side, r_m should be taken positive (i.e. $C \leq 1{,}7$), otherwise negative (i.e. $C > 1{,}7$).

In the following cases, r_m should be taken as 1,0 (i.e. $C = 0{,}7$):
- for braced members in which the first order moments arise only from or predominantly due to imperfections or transverse loading
- for unbraced members in general

(2) In cases with biaxial bending, the slenderness criterion may be checked separately for each direction. Depending on the outcome of this check, second order effects (a) may be ignored in both directions, (b) should be taken into account in one direction, or (c) should be taken into account in both directions.

5.8.3.2 Slenderness and effective length of isolated members

(1) The slenderness ratio is defined as follows:

$$\lambda = l_0 \, / \, i \tag{5.14}$$

where:
  l_0 is the effective length, see 5.8.3.2 (2) to (7)
  i is the radius of gyration of the uncracked concrete section

(2) For a general definition of the effective length, see 5.8.1. Examples of effective length for isolated members with constant cross section are given in Figure 5.7.

a) $l_0 = l$ b) $l_0 = 2l$ c) $l_0 = 0{,}7l$ d) $l_0 = l \, / \, 2$ e) $l_0 = l$ f) $l \, / 2 < l_0 < l$ g) $l_0 > 2l$
Figure 5.7: Examples of different buckling modes and corresponding effective lengths for isolated members

(3) For compression members in regular frames, the slenderness criterion (see 5.8.3.1) should be checked with an effective length l_0 determined in the following way:

Braced members (see Figure 5.7 (f)):

$$l_0 = 0{,}5l \cdot \sqrt{\left(1 + \frac{k_1}{0{,}45 + k_1}\right) \cdot \left(1 + \frac{k_2}{0{,}45 + k_2}\right)} \tag{5.15}$$

Unbraced members (see Figure 5.7 (g)):

$$l_0 = l \cdot \max\left\{ \sqrt{1 + 10 \cdot \frac{k_1 \cdot k_2}{k_1 + k_2}} \; ; \; \left(1 + \frac{k_1}{1 + k_1}\right)\left(1 + \frac{k_2}{1 + k_2}\right) \right\} \tag{5.16}$$

where:
  k_1, k_2 are the relative flexibilities of rotational restraints at ends 1 and 2 respectively:

k = $(\theta / M)\cdot (EI/l)$

θ is the rotation of restraining members for bending moment M;
    see also Figure 5.7 (f) and (g)

EI is the bending stiffness of compression member, see also 5.8.3.2 (4) and (5)

l is the clear height of compression member between end restraints

Note: $k = 0$ is the theoretical limit for rigid rotational restraint, and $k = \infty$ represents the limit for no restraint at all. Since fully rigid restraint is rare in practise, a minimum value of 0,1 is recommended for k_1 and k_2.

(4) If an adjacent compression member (column) in a node is likely to contribute to the rotation at buckling, then (EI/l) in the definition of k should be replaced by [$(EI/l)_a + (EI/l)_b$], a and b representing the compression member (column) above and below the node.

(5) In the definition of effective lengths, the stiffness of restraining members should include the effect of cracking, unless they can be shown to be uncracked in ULS.

(6) For other cases than those in (2) and (3), e.g. members with varying normal force and/or cross section, the criterion in 5.8.3.1 should be checked with an effective length based on the buckling load (calculated e.g. by a numerical method):

$$l_0 = \pi\sqrt{EI / N_B} \tag{5.17}$$

where:

    EI is a representative bending stiffness

    N_B is buckling load expressed in terms of this EI
         (in Expression (5.14), i should also correspond to this EI)

(7) The restraining effect of transverse walls may be allowed for in the calculation of the effective length of walls by the factor β given in 12.6.5.1. In Expression (12.9) and Table 12.1, l_w is then substituted by l_0 determined according to 5.8.3.2.

5.8.3.3 Global second order effects in buildings

(1) As an alternative to 5.8.2 (6), global second order effects in buildings may be ignored if

$$F_{V,Ed} \leq k_1 \cdot \frac{n_s}{n_s + 1,6} \cdot \frac{\sum E_{cd} I_c}{L^2} \tag{5.18}$$

where:

    $F_{V,Ed}$ is the total vertical load (on braced *and* bracing members)

    n_s is the number of storeys

    L is the total height of building above level of moment restraint

    E_{cd} is the design value of the modulus of elasticity of concrete, see 5.8.6 (3)

    I_c is the second moment of area (uncracked concrete section) of bracing member(s)

Note: The value of k_1 for use in a Country may be found in its National Annex. The recommended value is 0,31.

Expression (5.18) is valid only if all the following conditions are met:
- torsional instability is not governing, i.e. structure is reasonably symmetrical
- global shear deformations are negligible (as in a bracing system mainly consisting of shear walls without large openings)
- bracing members are rigidly fixed at the base, i.e. rotations are negligible

- the stiffness of bracing members is reasonably constant along the height
- the total vertical load increases by approximately the same amount per storey

(2) k_1 in Expression (5.18) may be replaced by k_2 if it can be verified that bracing members are uncracked in ultimate limit state.

Note 1: The value of k_2 for use in a Country may be found in its National Annex. The recommended value is 0,62.

Note 2: For cases where the bracing system has significant global shear deformations and/or end rotations, see Annex H (which also gives the background to the above rules).

5.8.4 Creep

(1)P The effect of creep shall be taken into account in second order analysis, with due consideration of both the general conditions for creep (see 3.1.4) and the duration of different loads in the load combination considered.

(2) The duration of loads may be taken into account in a simplified way by means of an effective creep ratio, φ_{ef}, which, used together with the design load, gives a creep deformation (curvature) corresponding to the quasi-permanent load:

$$\varphi_{ef} = \varphi_{(\infty,t0)} \cdot M_{0Eqp} / M_{0Ed} \tag{5.19}$$

where:

$\varphi_{(\infty,t0)}$ is the final creep coefficient according to 3.1.4
M_{0Eqp} is the first order bending moment in quasi-permanent load combination (SLS)
M_{0Ed} is the first order bending moment in design load combination (ULS)

Note. It is also possible to base φ_{ef} on total bending moments M_{Eqp} and M_{Ed}, but this requires iteration and a verification of stability under quasi-permanent load with $\varphi_{ef} = \varphi_{(\infty,t0)}$.

(3) If M_{0Eqp} / M_{0Ed} varies in a member or structure, the ratio may be calculated for the section with maximum moment, or a representative mean value may be used.

(4) The effect of creep may be ignored, i.e. $\varphi_{ef} = 0$ may be assumed, if the following three conditions are met:
- $\varphi_{(\infty,t0)} \leq 2$
- $\lambda \leq 75$
- $M_{0Ed}/N_{Ed} \geq h$

Here M_{0Ed} is the first order moment and h is the cross section depth in the corresponding direction.

Note. If the conditions for neglecting second order effects according to 5.8.2 (6) or 5.8.3.3 are only just achieved, it may be too unconservative to neglect both second order effects and creep, unless the mechanical reinforcement ratio (ω, see 5.8.3.1 (1)) is at least 0,25.

5.8.5 Methods of analysis

(1) The methods of analysis include a general method, based on non-linear second order analysis, see 5.8.6 and the following two simplified methods:
   (a) Method based on nominal stiffness, see 5.8.7
   (b) Method based on nominal curvature, see 5.8.8

Note 1: The selection of Simplified Method (a) and (b) to be used in a Country may be found in its National Annex.

Note 2: Nominal second order moments provided by the simplified methods (a) and (b) are sometimes greater than those corresponding to instability. This is to ensure that the total moment is compatible with the cross section resistance.

(2) Method (a) may be used for both isolated members and whole structures, if nominal stiffness values are estimated appropriately; see 5.8.7.

(3) Method (b) is mainly suitable for isolated members; see 5.8.8. However, with realistic assumptions concerning the distribution of curvature, the method in 5.8.8 can also be used for structures.

5.8.6 General method

(1)P The general method is based on non-linear analysis, including geometric non-linearity i.e. second order effects. The general rules for non-linear analysis given in 5.7 apply.

(2)P Stress-strain curves for concrete and steel suitable for overall analysis shall be used. The effect of creep shall be taken into account.

(3) Stress-strain relationships for concrete and steel given in 3.1.5, Expression (3.14) and 3.2.3 (Figure 3.8) may be used. With stress-strain diagrams based on design values, a design value of the ultimate load is obtained directly from the analysis. In Expression (3.14), and in the k-value, f_{cm} is then substituted by the design compressive strength f_{cd} and E_{cm} is substituted by

$$E_{cd} = E_{cm}/\gamma_{cE} \hspace{4cm} (5.20)$$

Note: The value of γ_{cE} for use in a Country may be found in its National Annex. The recommended value is 1,2.

(4) In the absence of more refined models, creep may be taken into account by multiplying all strain values in the concrete stress-strain diagram according to 5.8.6 (3) with a factor $(1 + \varphi_{ef})$, where φ_{ef} is the effective creep ratio according to 5.8.4.

(5) The favourable effect of tension stiffening may be taken into account.

Note: This effect is favourable, and may always be ignored, for simplicity.

(6) Normally, conditions of equilibrium and strain compatibility are satisfied in a number of cross sections. A simplified alternative is to consider only the critical cross section(s), and to assume a relevant variation of the curvature in between, e.g. similar to the first order moment or simplified in another appropriate way.

5.8.7 Method based on nominal stiffness

5.8.7.1 General

(1) In a second order analysis based on stiffness, nominal values of the flexural stiffness should be used, taking into account the effects of cracking, material non-linearity and creep on the overall behaviour. This also applies to adjacent members involved in the analysis, e.g. beams, slabs or foundations. Where relevant, soil-structure interaction should be taken into account.

(2) The resulting design moment is used for the design of cross sections with respect to bending moment and axial force according to 6.1, as compared with 5.8.6 (2).

5.8.7.2 Nominal stiffness

(1) The following model may be used to estimate the nominal stiffness of slender compression members with arbitrary cross section:

$$EI = K_c E_{cd} I_c + K_s E_s I_s \qquad (5.21)$$

where:
E_{cd} is the design value of the modulus of elasticity of concrete, see 5.8.6 (3)
I_c is the moment of inertia of concrete cross section
E_s is the design value of the modulus of elasticity of reinforcement, 5.8.6 (3)
I_s is the second moment of area of reinforcement, about the centre of area of the concrete
K_c is a factor for effects of cracking, creep etc, see 5.8.7.2 (2) or (3)
K_s is a factor for contribution of reinforcement, see 5.8.7.2 (2) or (3)

(2) The following factors may be used in Expression (5.21), provided $\rho \geq 0,002$:

$$K_s = 1$$
$$K_c = k_1 k_2 \,/\, (1 + \varphi_{ef}) \qquad (5.22)$$
where:
ρ is the geometric reinforcement ratio, A_s/A_c
A_s is the total area of reinforcement
A_c is the area of concrete section
φ_{ef} is the effective creep ratio, see 5.8.4
k_1 is a factor which depends on concrete strength class, Expression (5.23)
k_2 is a factor which depends on axial force and slenderness, Expression (5.24)

$$k_1 = \sqrt{f_{ck} \,/\, 20} \ \text{ (MPa)} \qquad (5.23)$$

$$k_2 = n \cdot \frac{\lambda}{170} \ \leq 0,20 \qquad (5.24)$$
where:
n is the relative axial force, $N_{Ed} \,/\, (A_c f_{cd})$
λ is the slenderness ratio, see 5.8.3

If the slenderness ratio λ is not defined, k_2 may be taken as

$$k_2 = n \cdot 0,30 \leq 0,20 \qquad (5.25)$$

(3) As a simplified alternative, provided $\rho \geq 0,01$, the following factors may be used in Expression (5.21):

$$K_s = 0$$
$$K_c = 0,3 \,/\, (1 + 0,5\varphi_{ef}) \qquad (5.26)$$

Note. The simplified alternative may be suitable as a preliminary step, followed by a more accurate calculation according to (2).

(4) In statically indeterminate structures, unfavourable effects of cracking in adjacent members should be taken into account. Expressions (5.21-5.26) are not generally applicable to such members. Partial cracking and tension stiffening may be taken into account e.g. according to 7.4.3. However, as a simplification, fully cracked sections may be assumed. The stiffness should be based on an effective concrete modulus:

$$E_{cd,eff} = E_{cd}/(1+\varphi_{ef})$$ (5.27)

where:

E_{cd} is the design value of the modulus of elasticity according to 5.8.6 (3)

φ_{ef} is the effective creep ratio; same value as for columns may be used

5.8.7.3 Moment magnification factor

(1) The total design moment, including second order moment, may be expressed as a magnification of the bending moments resulting from a linear analysis, namely:

$$M_{Ed} = M_{0Ed}\left[1 + \frac{\beta}{(N_B / N_{Ed}) - 1}\right]$$ (5.28)

where:

M_{0Ed} is the first order moment; see also 5.8.8.2 (2)

β is a factor which depends on distribution of 1st and 2nd order moments, see 5.8.7.3 (2)-(3)

N_{Ed} is the design value of axial load

N_B is the buckling load based on nominal stiffness

(2) For isolated members with constant cross section and axial load, the second order moment may normally be assumed to have a sine-shaped distribution. Then

$$\beta = \pi^2 / c_0$$ (5.29)

where:

c_0 is a coefficient which depends on the distribution of first order moment (for instance, $c_0 = 8$ for a constant first order moment, $c_0 = 9{,}6$ for a parabolic and 12 for a symmetric triangular distribution etc.).

(3) For members without transverse load, differing first order end moments M_{01} and M_{02} may be replaced by an equivalent constant first order moment M_{0e} according to 5.8.8.2 (2). Consistent with the assumption of a constant first order moment, $c_0 = 8$ should be used.

Note: The value of $c_0 = 8$ also applies to members bent in double curvature. It should be noted that in some cases, depending on slenderness and axial force, the end moments(s) can be greater than the magnified equivalent moment

(4) Where 5.8.7.3 (2) or (3) is not applicable, $\beta = 1$ is normally a reasonable simplification. Expression (5.28) can then be reduced to:

$$M_{Ed} = \frac{M_{0Ed}}{1 - (N_{Ed} / N_B)}$$ (5.30)

Note: 5.8.7.3 (4) is also applicable to the global analysis of certain types of structures, e.g. structures braced by shear walls and similar, where the principal action effect is bending moment in bracing units. For other types of structures, a more general approach is given in Annex H, Clause H.2.

5.8.8 Method based on nominal curvature

5.8.8.1 General

(1) This method is primarily suitable for isolated members with constant normal force and a defined effective length l_0 (see 5.8.3.2). The method gives a nominal second order moment based on a deflection, which in turn is based on the effective length and an estimated maximum curvature (see also 5.8.5(4)).

(2) The resulting design moment is used for the design of cross sections with respect to bending moment and axial force according to 6.1.

5.8.8.2 Bending moments

(1) The design moment is:

$$M_{Ed} = M_{0Ed} + M_2 \qquad (5.31)$$

where:
    M_{0Ed} is the 1st order moment, including the effect of imperfections, see also 5.8.8.2 (2)
    M_2 is the nominal 2nd order moment, see 5.8.8.2 (3)

The maximum value of M_{Ed} is given by the distributions of M_{0Ed} and M_2; the latter may be taken as parabolic or sinusoidal over the effective length.

Note: For statically indeterminate members, M_{0Ed} is determined for the actual boundary conditions, whereas M_2 will depend on boundary conditions via the effective length, cf. 5.8.8.1 (1).

(2) Differing first order end moments M_{01} and M_{02} may be replaced by an equivalent first order end moment M_{0e}:

$$M_{0e} = 0{,}6\, M_{02} + 0{,}4\, M_{01} \geq 0{,}4\, M_{02} \qquad (5.32)$$

M_{01} and M_{02} should have the same sign if they give tension on the same side, otherwise opposite signs. Furthermore, $\left| M_{02} \right| \geq \left| M_{01} \right|$.

(3) The nominal second order moment M_2 in Expression (5.31) is

$$M_2 = N_{Ed}\, e_2 \qquad (5.33)$$

where:
    N_{Ed} is the design value of axial force
    e_2 is the deflection = $(1/r)\, l_0^2 / c$
    $1/r$ is the curvature, see 5.8.8.3
    l_0 is the effective length, see 5.8.3.2
    c is a factor depending on the curvature distribution, see 5.8.8.2 (4)

(4) For constant cross section, $c = 10$ ($\approx \pi^2$) is normally used. If the first order moment is constant, a lower value should be considered (8 is a lower limit, corresponding to constant total moment).

Note. The value π^2 corresponds to a sinusoidal curvature distribution. The value for constant curvature is 8. Note that c depends on the distribution of the *total* curvature, whereas c_0 in 5.8.7.3 (2) depends on the curvature corresponding to the first order moment only.

5.8.8.3 Curvature

(1) For members with constant symmetrical cross sections (incl. reinforcement), the following may be used:

$$1/r = K_r \cdot K_\varphi \cdot 1/r_0 \qquad\qquad (5.34)$$

where:

K_r is a correction factor depending on axial load, see 5.8.8.3 (3)
K_φ is a factor for taking account of creep, see 5.8.8.3 (4)
$1/r_0 = \varepsilon_{yd} / (0,45\ d)$
$\varepsilon_{yd} = f_{yd} / E_s$
d is the effective depth; see also 5.8.8.3 (2)

(2) If all reinforcement is not concentrated on opposite sides, but part of it is distributed parallel to the plane of bending, d is defined as

$$d = (h/2) + i_s \qquad\qquad (5.35)$$

where i_s is the radius of gyration of the total reinforcement area

(3) K_r in Expression (5.34) should be taken as:

$$K_r = (n_u - n) / (n_u - n_{bal}) \le 1 \qquad\qquad (5.36)$$

where:

$n \quad = N_{Ed} / (A_c\ f_{cd})$, relative axial force
N_{Ed} is the design value of axial force
$n_u \quad = 1 + \omega$
n_{bal} is the value of n at maximum moment resistance; the value 0,4 may be used
$\omega \quad = A_s\ f_{yd} / (A_c\ f_{cd})$
$A_s \quad$ is the total area of reinforcement
$A_c \quad$ is the area of concrete cross section

(4) The effect of creep should be taken into account by the following factor:

$$K_\varphi = 1 + \beta\varphi_{ef} \ge 1 \qquad\qquad (5.37)$$

where:

φ_{ef} is the effective creep ratio, see 5.8.4
$\beta \quad = 0,35 + f_{ck}/200 - \lambda/150$
$\lambda \quad$ is the slenderness ratio, see 5.8.3.1

5.8.9 Biaxial bending

(1) The general method described in 5.8.6 may also be used for biaxial bending. The following provisions apply when simplified methods are used. Special care should be taken to identify the section along the member with the critical combination of moments.

(2) Separate design in each principal direction, disregarding biaxial bending, may be made as a first step. Imperfections need to be taken into account only in the direction where they will have the most unfavourable effect.

(3) No further check is necessary if the slenderness ratios satisfy the following two conditions

$$\lambda_y/\lambda_z \le 2 \quad \text{and} \quad \lambda_z/\lambda_y \le 2 \qquad\qquad (5.38\text{a})$$

and if the relative eccentricities e_y/h and e_z/b (see Figure 5.7) satisfy one the following conditions:

$$\frac{e_y/h_{eq}}{e_z/b_{eq}} \le 0{,}2 \quad \text{or} \quad \frac{e_z/b_{eq}}{e_y/h_{eq}} \le 0{,}2 \qquad\qquad (5.38\text{b})$$

where:

    b, h are the width and depth of the section

    $b_{eq} = i_y \cdot \sqrt{12}$ and $h_{eq} = i_z \cdot \sqrt{12}$ for an equivalent rectangular section

    λ_y, λ_z are the slenderness ratios l_0/i with respect to y- and z-axis respectively

    i_y, i_z are the radii of gyration with respect to y- and z-axis respectively

    e_z = M_{Edy} / N_{Ed}; eccentricity along z-axis

    e_y = M_{Edz} / N_{Ed}; eccentricity along y-axis

    M_{Edy} is the design moment about y-axis, including second order moment

    M_{Edz} is the design moment about z-axis, including second order moment

    N_{Ed} is the design value of axial load in the respective load combination
Figure 5.8.   Definition of eccentricities e_y and e_z.

(4) If the condition of Expression (5.38) is not fulfilled, biaxial bending should be taken into account including the 2nd order effects in each direction (unless they may be ignored according to 5.8.2 (6) or 5.8.3). In the absence of an accurate cross section design for biaxial bending, the following simplified criterion may be used:

$$\left(\frac{M_{Edz}}{M_{Rdz}}\right)^a + \left(\frac{M_{Edy}}{M_{Rdy}}\right)^a \le 1{,}0 \qquad\qquad (5.39)$$

where:

$M_{Edz/y}$ is the design moment around the respective axis, including a 2nd order moment.

$M_{Rdz/y}$ is the moment resistance in the respective direction

a   is the exponent;

for circular and elliptical cross sections: a = 2

for rectangular cross sections:

N_{Ed}/N_{Rd}	0,1	0,7	1,0
a =	1,0	1,5	2,0

with linear interpolation for intermediate values

N_{Ed} is the design value of axial force

N_{Rd} = $A_c f_{cd} + A_s f_{yd}$, design axial resistance of section.

where:

A_c is the gross area of the concrete section

A_s is the area of longitudinal reinforcement

5.9 Lateral instability of slender beams

(1)P Lateral instability of slender beams shall be taken into account where necessary, e.g. for precast beams during transport and erection, for beams without sufficient lateral bracing in the finished structure etc. Geometric imperfections shall be taken into account.

(2) A lateral deflection of l / 300 should be assumed as a geometric imperfection in the verification of beams in unbraced conditions, with l = total length of beam. In finished structures, bracing from connected members may be taken into account

(3) Second order effects in connection with lateral instability may be ignored if the following conditions are fulfilled:

- persistent situations: $\dfrac{l_{0t}}{b} \leq \dfrac{50}{\left(h/b\right)^{1/3}}$ and $h/b \leq 2{,}5$ (5.40a)

- transient situations: $\dfrac{l_{0t}}{b} \leq \dfrac{70}{\left(h/b\right)^{1/3}}$ and $h/b \leq 3{,}5$ (5.40b)

where:

l_{0t} is the distance between torsional restraints

h is the total depth of beam in central part of l_{0t}

b is the width of compression flange

(4) Torsion associated with lateral instability should be taken into account in the design of supporting structures.

5.10 Prestressed members and structures

5.10.1 General

(1)P The prestress considered in this Standard is that applied to the concrete by stressed tendons.

(2) The effects of prestressing may be considered as an action or a resistance caused by prestrain and precurvature. The bearing capacity should be calculated accordingly.

(3) In general prestress is introduced in the action combinations defined in EN 1990 as part of the loading cases and its effects should be included in the applied internal moment and axial force.

(4) Following the assumptions of (3) above, the contribution of the prestressing tendons to the resistance of the section should be limited to their additional strength beyond prestressing. This may be calculated assuming that the origin of the stress/strain relationship of the tendons is displaced by the effects of prestressing.

(5)P Brittle failure of the member caused by failure of prestressing tendons shall be avoided.

(6) Brittle failure should be avoided by one or more of the following methods:

Method A: Provide minimum reinforcement in accordance with 9.2.1.

Method B: Provide pretensioned bonded tendons.

Method C: Provide easy access to prestressed concrete members in order to check and control the condition of tendons by non-destructive methods or by monitoring.

Method D: Provide satisfactory evidence concerning the reliability of the tendons.

Method E: Ensure that if failure were to occur due to either an increase of load or a reduction of prestress under the frequent combination of actions, cracking would occur before the ultimate capacity would be exceeded, taking account of moment redistribution due to cracking effects.

Note: The selection of Methods to be used in a Country may be found in its National Annex.

5.10.2 Prestressing force during tensioning

5.10.2.1 Maximum stressing force

(1)P The force applied to a tendon, P_{max} (i.e. the force at the active end during tensioning) shall not exceed the following value:

$$P_{max} = A_p \cdot \sigma_{p,max} \tag{5.41}$$

where:
A_p is the cross-sectional area of the tendon
$\sigma_{p,max}$ is the maximum stress applied to the tendon
       $= \min \{ k_1 \cdot f_{pk} ; k_2 \cdot f_{p0,1k} \}$

Note: The values of k_1 and k_2 for use in a Country may be found in its National Annex. The recommended values are $k_1 = 0{,}8$ and $k_2 = 0{,}9$

(2) Overstressing is permitted if the force in the jack can be measured to an accuracy of $\pm$ 5 % of the final value of the prestressing force. In such cases the maximum prestressing force P_{max} may be increased to $k_3 \cdot f_{p0,1k}$ (e.g. for the occurrence of an unexpected high friction in long-line pretensioning).

Note: The values of k_3 for use in a Country may be found in its National Annex. The recommended value is 0,95.

5.10.2.2 Limitation of concrete stress

(1)P Local concrete crushing or splitting at the end of pre- and post-tensioned members shall be avoided.

(2) Local concrete crushing or splitting behind post-tensioning anchors should be avoided in accordance with the relevant European Technical Approval.

(3) The strength of concrete at application of or transfer of prestress should not be less than the minimum value defined in the relevant European Technical Approval.

(4) If prestress in an individual tendon is applied in steps, the required concrete strength may be reduced. The minimum strength $f_{cm}(t)$ at the time t should be k_4 [%] of the required concrete strength for full prestressing given in the European Technical Approval. Between the minimum strength and the required concrete strength for full prestressing, the prestress may be interpolated between k_5 [%] and 100% of the full prestressing.

> **Note:** The values of k_4 and k_5 for use in a Country may be found in its National Annex. The recommended value for k_4 is 50 and for k_5 is 30.

(5) The concrete compressive stress in the structure resulting from the prestressing force and other loads acting at the time of tensioning or release of prestress, should be limited to:

$$\sigma_c \leq 0,6\, f_{ck}(t) \tag{5.42}$$

where $f_{ck}(t)$ is the characteristic compressive strength of the concrete at time t when it is subjected to the prestressing force.

For pretensioned elements the stress at the time of transfer of prestress may be increased to $k_6 \cdot f_{ck}(t)$, if it can be justified by tests or experience that longitudinal cracking is prevented.

> **Note:** The value of k_6 for use in a Country may be found in its National Annex. The recommended value is 0,7.

If the compressive stress permanently exceeds $0,45\, f_{ck}(t)$ the non-linearity of creep should be taken into account.

5.10.2.3 Measurements

(1)P In post-tensioning the prestressing force and the related elongation of the tendon shall be checked by measurements and the actual losses due to friction shall be controlled.

5.10.3 Prestress force

(1)P At a given time t and distance x (or arc length) from the active end of the tendon the mean prestress force $P_{m,t}(x)$ is equal to the maximum force P_{max} imposed at the active end, minus the immediate losses and the time dependent losses (see below). Absolute values are considered for all the losses.

(2) The value of the initial prestress force $P_{m0}(x)$ (at time $t = t0$) applied to the concrete immediately after tensioning and anchoring (post-tensioning) or after transfer of prestressing (pre-tensioning) is obtained by subtracting from the force at tensioning P_{max} the immediate losses $\Delta P_i(x)$ and should not exceed the following value:

$$P_{m0}(x) = A_p \cdot \sigma_{pm0}(x) \tag{5.43}$$

where:

$\sigma_{pm0}(x)$ is the stress in the tendon immediately after tensioning or transfer

$= \min \{ k_7 \cdot f_{pk} ; k_8 f_{p0,1k} \}$

Note: The values of k_7 and k_8 for use in a Country may be found in its National Annex. The recommended value for k_7 is 0,75 and for k_8 is 0,85

(3) When determining the immediate losses $\Delta P_i(x)$ the following immediate influences should be considered for pre-tensioning and post-tensioning where relevant (see 5.10.4 and 5.10.5):
- losses due to elastic deformation of concrete ΔP_{el}
- losses due to short term relaxation ΔP_r
- losses due to friction $\Delta P_\mu(x)$
- losses due to anchorage slip ΔP_{sl}

(4) The mean value of the prestress force $P_{m,t}(x)$ at the time $t > t0$ should be determined with respect to the prestressing method. In addition to the immediate losses given in (3) the time-dependent losses of prestress $\Delta P_{c+s+r}(x)$ (see 5.10.6) as a result of creep and shrinkage of the concrete and the long term relaxation of the prestressing steel should be considered and $P_{m,t}(x)$ $= P_{m0}(x) - \Delta P_{c+s+r}(x)$.

5.10.4 Immediate losses of prestress for pre-tensioning

(1) The following losses occurring during pre-tensioning should be considered:

(i) during the stressing process: loss due to friction at the bends (in the case of curved wires or strands) and losses due to wedge draw-in of the anchorage devices.

(ii) before the transfer of prestress to concrete: loss due to relaxation of the pretensioning tendons during the period which elapses between the tensioning of the tendons and prestressing of the concrete.

Note: In case of heat curing, losses due to shrinkage and relaxation are modified and should be assessed accordingly; direct thermal effect should also be considered (see Annex D)

(iii) at the transfer of prestress to concrete: loss due to elastic deformation of concrete as the result of the action of pre-tensioned tendons when they are released from the anchorages.

5.10.5 Immediate losses of prestress for post-tensioning

5.10.5.1 Losses due to the instantaneous deformation of concrete

(1) Account should be taken of the loss in tendon force corresponding to the deformation of concrete, taking account the order in which the tendons are stressed.

(2) This loss, ΔP_{el}, may be assumed as a mean loss in each tendon as follows:

$$\Delta P_{el} = A_p \cdot E_p \cdot \sum \left[\frac{j \cdot \Delta \sigma_c(t)}{E_{cm}(t)} \right] \tag{5.44}$$

where:

$\Delta \sigma_c(t)$ is the variation of stress at the centre of gravity of the tendons applied at time t

> j is a coefficient equal to
> > $(n-1)/2n$ where n is the number of identical tendons successively
> > > prestressed. As an approximation j may be taken as 1/2
> > 1   for the variations due to permanent actions applied after prestressing.

5.10.5.2 Losses due to friction

(1) The losses due to friction $\Delta P_\mu(x)$ in post-tensioned tendons may be estimated from:

$$\Delta P_\mu(x) = P_{max}\,(1 - e^{-\mu(\theta + kx)}) \tag{5.45}$$

where:
> θ is the sum of the angular displacements over a distance x (irrespective of direction or sign)
> μ is the coefficient of friction between the tendon and its duct
> k is an unintentional angular displacement for internal tendons (per unit length)
> x is the distance along the tendon from the point where the prestressing force is equal to P_{max} (the force at the active end during tensioning)

The values μ and k are given in the relevant European Technical Approval. The value μ depends on the surface characteristics of the tendons and the duct, on the presence of rust, on the elongation of the tendon and on the tendon profile.

The value k for unintentional angular displacement depends on the quality of workmanship, on the distance between tendon supports, on the type of duct or sheath employed, and on the degree of vibration used in placing the concrete.

(2) In the absence of data given in a European Technical Approval the values for μ given in Table 5.1 may be assumed, when using Expression (5.45).

(3) In the absence of data in a European Technical Approval, values for unintended regular displacements for internal tendons will generally be in the range $0{,}005 < k < 0{,}01$ per metre.

(4) For external tendons, the losses of prestress due to unintentional angles may be ignored.

Table 5.1: Coefficients of friction μ of post-tensioned internal tendons and external unbonded tendons

	Internal tendons [1]	External unbonded tendons			
		Steel duct/ non lubricated	HDPE duct/ non lubricated	Steel duct/ lubricated	HDPE duct/ lubricated
Cold drawn wire	0,17	0,25	0,14	0,18	0,12
Strand	0,19	0,24	0,12	0,16	0,10
Deformed bar	0,65	-	-	-	-
Smooth round bar	0,33	-	-	-	-
[1] for tendons which fill about half of the duct					

Note: HPDE - High density polyethylene

5.10.5.3 Losses at anchorage

(1) Account should be taken of the losses due to wedge draw-in of the anchorage devices, during the operation of anchoring after tensioning, and due to the deformation of the anchorage itself.

(2) Values of the wedge draw-in are given in the European Technical Approval.

5.10.6 Time dependent losses of prestress for pre- and post-tensioning

(1) The time dependent losses may be calculated by considering the following two reductions of stress:

  (a) due to the reduction of strain, caused by the deformation of concrete due to creep and shrinkage, under the permanent loads:

  (b) the reduction of stress in the steel due to the relaxation under tension.

  Note: The relaxation of steel depends on the concrete deformation due to creep and shrinkage. This interaction can generally and approximately be taken into account by a reduction factor 0,8.

(2) A simplified method to evaluate time dependent losses at location x under the permanent loads is given by Expression (5.46).

$$\Delta P_{c+s+r} = A_p \Delta\sigma_{p,c+s+r} = A_p \frac{\varepsilon_{cs}E_p + 0{,}8\Delta\sigma_{pr} + \dfrac{E_p}{E_{cm}}\varphi(t,t_0).\sigma_{c,QP}}{1 + \dfrac{E_p}{E_{cm}}\dfrac{A_p}{A_c}\left(1 + \dfrac{A_c}{I_c}z_{cp}^2\right)[1 + 0{,}8\,\varphi(t,t_0)]} \tag{5.46}$$

where:

$\Delta\sigma_{p,c+s+r}$ is the absolute value of the variation of stress in the tendons due to creep, shrinkage and relaxation at location x, at time t

ε_{cs} is the estimated shrinkage strain according to 3.1.4(6) in absolute value

E_p is the modulus of elasticity for the prestressing steel, see 3.3.3 (9)

E_{cm} is the modulus of elasticity for the concrete (Table 3.1)

$\Delta\sigma_{pr}$ is the absolute value of the variation of stress in the tendons at location x, at time t, due to the relaxation of the prestressing steel. It is determined for a stress of $\sigma_p = \sigma_p(G + P_{m0} + \psi_2 Q)$
where $\sigma_p = \sigma_p(G + P_{m0} + \psi_2 Q)$ is the initial stress in the tendons due to initial prestress and quasi-permanent actions.

$\varphi(t,t_0)$ is the creep coefficient at a time t and load application at time t_0

$\sigma_{c,QP}$ is the stress in the concrete adjacent to the tendons, due to self-weight and initial prestress and other quasi-permanent actions where relevant. The value of $\sigma_{c,QP}$ may be the effect of part of self-weight and initial prestress or the effect of a full quasi-permanent combination of action ($\sigma_c(G + P_{m0} + \psi_2 Q)$), depending on the stage of construction considered.

A_p is the area of all the prestressing tendons at the location x

A_c is the area of the concrete section.

I_c is the second moment of area of the concrete section.

z_{cp} is the distance between the centre of gravity of the concrete section and the tendons

Compressive stresses and the corresponding strains given in Expression (5.46) should be used with a positive sign.

(3) Expression (5.46) applies for bonded tendons when local values of stresses are used and for unbonded tendons when mean values of stresses are used. The mean values should be calculated between straight sections limited by the idealised deviation points for external tendons or along the entire length in case of internal tendons.

5.10.7 Consideration of prestress in analysis

(1) Second order moments can arise from prestressing with external tendons.

(2) Moments from secondary effects of prestressing arise only in statically indeterminate structures.

(3) For linear analysis both the primary and secondary effects of prestressing should be applied before any redistribution of forces and moments is considered (see 5.5).

(4) In plastic and non-linear analysis the secondary effect of prestress may be treated as additional plastic rotations which should then be included in the check of rotation capacity.

(5) Rigid bond between steel and concrete may be assumed after grouting of post-tensioned tendons. However before grouting the tendons should be considered as unbonded.

(6) External tendons may be assumed to be straight between deviators.

5.10.8 Effects of prestressing at ultimate limit state

(1) In general the design value of the prestressing force may be determined by $P_{d,t}(x) = \gamma_P, P_{m,t}(x)$ (see 5.10.3 (4) for the definition of $P_{m,t}(x)$) and 2.4.2.2 for γ_p.

(2) For prestressed members with permanently unbonded tendons, it is generally necessary to take the deformation of the whole member into account when calculating the increase of the stress in the prestressing steel. If no detailed calculation is made, it may be assumed that the increase of the stress from the effective prestress to the stress in the ultimate limit state is $\Delta\sigma_{p,ULS}$.

> **Note:** The value of $\Delta\sigma_{p,ULS}$ for use in a Country may be found in its National Annex. The recommended value is 100 MPa.

(3) If the stress increase is calculated using the deformation state of the whole member the mean values of the material properties should be used. The design value of the stress increase $\Delta\sigma_{pd} = \Delta\sigma_p \cdot \gamma_{\Delta P}$ should be determined by applying partial safety factors $\gamma_{\Delta P,sup}$ and $\gamma_{\Delta P,inf}$ respectively.

> **Note:** The values of $\gamma_{\Delta P,sup}$ and $\gamma_{\Delta P,inf}$ for use in a Country may be found in its National Annex. The recommended values for $\gamma_{\Delta P,sup}$ and $\gamma_{\Delta P,inf}$ are 1,2 and 0,8 respectively. If linear analysis with uncracked sections is applied, a lower limit of deformations may be assumed and the recommended value for both $\gamma_{\Delta P,sup}$ and $\gamma_{\Delta P,inf}$ is 1,0.

5.10.9 Effects of prestressing at serviceability limit state and limit state of fatigue

(1)P For serviceability and fatigue calculations allowance shall be made for possible variations in prestress. Two characteristic values of the prestressing force at the serviceability limit state are estimated from:

$$P_{k,sup} = r_{sup}\, P_{m,t}\,(x) \tag{5.47}$$

$$P_{k,inf} = r_{inf}\, P_{m,t}(x) \tag{5.48}$$

where:
$P_{k,sup}$ is the upper characteristic value
$P_{k,inf}$ is the lower characteristic value

Note: The values of r_{sup} and r_{inf} for use in a Country may be found in its National Annex. The recommended values are:
- for pre-tensioning or unbonded tendons: r_{sup} = 1,05 and r_{inf} = 0,95
- for post-tensioning with bonded tendons: r_{sup} = 1,10 and r_{inf} = 0,90
- when appropriate measures (e.g. direct measurements of pretensioning) are taken: r_{sup} = r_{inf} = 1,0.

5.11 Analysis for some particular structural members

(1)P Slabs supported on columns are defined as flat slabs.

(2)P Shear walls are plain or reinforced concrete walls that contribute to lateral stability of the structure.

Note: For information concerning the analysis of flat slabs and shear walls see Annex I.

SECTION 6 ULTIMATE LIMIT STATES (ULS)

6.1   Bending with or without axial force

(1)P This section applies to undisturbed regions of beams, slabs and similar types of members for which sections remain approximately plane before and after loading. The discontinuity regions of beams and other members in which plane sections do not remain plane may be designed and detailed according to 6.5.

(2)P When determining the ultimate moment resistance of reinforced or prestressed concrete cross-sections, the following assumptions are made:
- plane sections remain plane.
- the strain in bonded reinforcement or bonded prestressing tendons, whether in tension or in compression, is the same as that in the surrounding concrete.
- the tensile strength of the concrete is ignored.
- the stresses in the concrete in compression are derived from the design stress/strain relationship given in 3.1.7.
- the stresses in the reinforcing or prestressing steel are derived from the design curves in 3.2 (Figure 3.8) and 3.3 (Figure 3.10).
- the initial strain in prestressing tendons is taken into account when assessing the stresses in the tendons.

(3)P The compressive strain in the concrete shall be limited to ε_{cu2}, or ε_{cu3}, depending on the stress-strain diagram used, see 3.1.7 and Table 3.1. The strains in the reinforcing steel and the prestressing steel shall be limited to ε_{ud} (where applicable); see 3.2.7 (2) and 3.3.6 (7) respectively.

(4)   For cross-sections with symmetrical reinforcement loaded by the compression force it is necessary to assume the minimum eccentricity, $e_0 = h/30$ but not less than 20 mm where h is the depth of the section.

(5)   In parts of cross-sections which are subjected to approximately concentric loading ($e/h < 0{,}1$), such as compression flanges of box girders, the mean compressive strain in that part of the section should be limited to ε_{c2} (or ε_{c3} if the bilinear relation of Figure 3.4 is used).

(6) The possible range of strain distributions is shown in Figure 6.1.

(7) For prestressed members with permanently unbonded tendons see 5.10.8.

(8) For external prestressing tendons the strain in the prestressing steel between two subsequent contact points (anchors or deviation saddles) is assumed to be constant. The strain in the prestressing steel is then equal to the initial strain, realised just after completion of the prestressing operation, increased by the strain resulting from the structural deformation between the contact areas considered. See also 5.10.

$\boxed{A}$ - **reinforcing steel tension strain limit**

$\boxed{B}$ - **concrete compression strain limit**

$\boxed{C}$ - **concrete pure compression strain limit**

Figure 6.1: Possible strain distributions in the ultimate limit state

6.2 Shear

6.2.1 General verification procedure

(1)P For the verification of the shear resistance the following symbols are defined:

$V_{Rd,c}$ is the design shear resistance of the member without shear reinforcement.

$V_{Rd,s}$ is the design value of the shear force which can be sustained by the yielding shear reinforcement.

$V_{Rd,max}$ is the design value of the maximum shear force which can be sustained by the member, limited by crushing of the compression struts.

In members with inclined chords the following additional values are defined (see Figure 6.2):

V_{ccd} is the design value of the shear component of the force in the compression area, in the case of an inclined compression chord.

V_{td} is the design value of the shear component of the force in the tensile reinforcement, in the case of an inclined tensile chord.
Figure 6.2: Shear component for members with inclined chords

(2)   The shear resistance of a member with shear reinforcement is equal to:

$$V_{Rd} = V_{Rd,s} + V_{ccd} + V_{td} \tag{6.1}$$

(3)   In regions of the member where $V_{Ed} \leq V_{Rd,c}$ no calculated shear reinforcement is necessary. V_{Ed} is the design shear force in the section considered resulting from external loading and prestressing (bonded or unbonded).

(4) When, on the basis of the design shear calculation, no shear reinforcement is required, minimum shear reinforcement should nevertheless be provided according to 9.2.2. The minimum shear reinforcement may be omitted in members such as slabs (solid, ribbed or hollow core slabs) where transverse redistribution of loads is possible. Minimum reinforcement may also be omitted in members of minor importance (e.g. lintels with span $\leq$ 2 m) which do not contribute significantly to the overall resistance and stability of the structure.

(5) In regions where V_{Ed} > $V_{Rd,c}$ according to Expression (6.2), sufficient shear reinforcement should be provided in order that $V_{Ed} \leq V_{Rd}$ (see Expression (6.8)).

(6) The sum of the design shear force and the contributions of the flanges, V_{Ed} - V_{ccd} - V_{td}, should not exceed the permitted maximum value $V_{Rd,max}$ (see 6.2.3), anywhere in the member.

(7) The longitudinal tension reinforcement should be able to resist the additional tensile force caused by shear (see 6.2.3 (7)).

(8) For members subject to predominantly uniformly distributed loading the design shear force need not to be checked at a distance less than d from the face of the support.   Any shear reinforcement required should continue to the support. In addition it should be verified that the shear at the support does not exceed $V_{Rd,max}$ (see also 6.2.2 (6) and 6.2.3 (8).

(9) Where a load is applied near the bottom of a section, sufficient vertical reinforcement to carry the load to the top of the section should be provided in addition to any reinforcement required to resist shear.

6.2.2 Members not requiring design shear reinforcement

(1) The design value for the shear resistance $V_{Rd,c}$ is given by:

$$V_{Rd,c} = [C_{Rd,c}k(100\, \rho_l\, f_{ck})^{1/3} + k_1\, \sigma_{cp}]\, b_w d \tag{6.2.a}$$

with a minimum of

$$V_{Rd,c} = (v_{min} + k_1 \sigma_{cp})\, b_w d \tag{6.2.b}$$

where:

f_{ck} is in MPa

$$k \quad = 1+\sqrt{\frac{200}{d}} \leq 2{,}0 \;\; \text{with } d \text{ in mm}$$

$$\rho_l \quad = \frac{A_{sl}}{b_w d} \leq 0{,}02$$

A_{sl} is the area of the tensile reinforcement, which extends $\geq$ (l_{bd} + d) beyond the section considered (see Figure 6.3).

b_w is the smallest width of the cross-section in the tensile area [mm]

σ_{cp} $= N_{Ed}/A_c < 0,2\ f_{cd}$ [MPa]

N_{Ed} is the axial force in the cross-section due to loading or prestressing [in N] ($N_{Ed}>0$ for compression). The influence of imposed deformations on N_E may be ignored.

A_C is the area of concrete cross section [mm^2]

$V_{Rd,c}$ is [N]

Note: The values of $C_{Rd,c}$, v_{min} and k_1 for use in a Country may be found in its National Annex. The recommended value for $C_{Rd,c}$ is $0,18/\gamma_c$, that for v_{min} is given by Expression (6.3N) and that for k_1 is 0,15.

$$v_{min} = 0,035\ k^{3/2} \cdot f_{ck}^{1/2} \tag{6.3N}$$

A - section considered
Figure 6.3: Definition of A_{sl} in Expression (6.2)

(2) In prestressed single span members without shear reinforcement, the shear resistance of the regions cracked in bending may be calculated using Expression (6.2a). In regions uncracked in bending (where the flexural tensile stress is smaller than $f_{ctk,0,05}/\gamma_c$) the shear resistance should be limited by the tensile strength of the concrete. In these regions the shear resistance is given by:

$$V_{Rd,c} = \frac{I \cdot b_w}{S} \sqrt{\left(f_{ctd}\right)^2 + \alpha_l \sigma_{cp} f_{ctd}} \tag{6.4}$$

where

I is the second moment of area

b_w is the width of the cross-section at the centroidal axis, allowing for the presence of ducts in accordance with Expressions (6.16) and (6.17)

S is the first moment of area above and about the centroidal axis

α_l $= l_x/l_{pt2} \le 1,0$ for pretensioned tendons
        $= 1,0$ for other types of prestressing

l_x is the distance of section considered from the starting point of the transmission length

l_{pt2} is the upper bound value of the transmission length of the prestressing element according to Expression (8.18).

σ_{cp} is the concrete compressive stress at the centroidal axis due to axial loading and/or prestressing ($\sigma_{cp} = N_{Ed}/A_c$ in MPa, $N_{Ed} > 0$ in compression)

For cross-sections where the width varies over the height, the maximum principal stress may occur on an axis other than the centroidal axis. In such a case the minimum value of the shear resistance should be found by calculating $V_{Rd,c}$ at various axes in the cross-section.

(3) The calculation of the shear resistance according to Expression (6.4) is not required for cross-sections that are nearer to the support than the point which is the intersection of the elastic centroidal axis and a line inclined from the inner edge of the support at an angle of 45°.

(4) For the general case of members subjected to a bending moment and an axial force, which can be shown to be uncracked in flexure at the ULS, reference is made to 12.6.3.

(5) For the design of the longitudinal reinforcement, in the region cracked in flexure, the M_{Ed} - line should be shifted over a distance $a_l = d$ in the unfavourable direction (see 9.2.1.3 (2)).

(6) For members with loads applied on the upper side within a distance $0,5d \leq a_v \leq 2d$ from the edge of a support (or centre of bearing where flexible bearings are used), the contribution of this load to the shear force V_{Ed} may be multiplied by $\beta = a_v/2d$. This reduction may be applied for checking $V_{Rd,c}$ in Expression (6.2.a). This is only valid provided that the longitudinal reinforcement is fully anchored at the support. For $a_v \leq 0,5d$ the value $a_v = 0,5d$ should be used.

The shear force V_{Ed}, calculated without reduction by β, should however always satisfy the condition

$$V_{Ed} \leq 0,5 \, b_w d \, \nu \, f_{cd} \tag{6.5}$$

where ν is a strength reduction factor for concrete cracked in shear

Note: The value ν for use in a Country may be found in its National Annex. The recommended value follows from:

$$\nu = 0,6\left[1 - \frac{f_{ck}}{250}\right] \qquad (f_{ck} \text{ in MPa}) \tag{6.6N}$$

    (a) Beam with direct support   **(b) Corbel**
Figure 6.4: Loads near supports

(7) Beams with loads near to supports and corbels may alternatively be designed with strut and tie models. For this alternative, reference is made to 6.5.

6.2.3 Members requiring design shear reinforcement

(1) The design of members with shear reinforcement is based on a truss model (Figure 6.5). Limiting values for the angle θ of the inclined struts in the web are given in 6.2.3 (2).

In Figure 6.5 the following notations are shown:

α is the angle between shear reinforcement and the beam axis perpendicular to the shear force (measured positive as shown in Figure 6.5)

θ is the angle between the concrete compression strut and the beam axis perpendicular to the shear force

F_{td} is the design value of the tensile force in the longitudinal reinforcement

F_{cd} is the design value of the concrete compression force in the direction of the longitudinal member axis.

b_w is the minimum width between tension and compression chords

z is the inner lever arm, for a member with constant depth, corresponding to the bending moment in the element under consideration. In the shear analysis of reinforced concrete without axial force, the approximate value $z = 0,9d$ may normally be used.

In elements with inclined prestressing tendons, longitudinal reinforcement at the tensile chord should be provided to carry the longitudinal tensile force due to shear defined in (3).

$\boxed{A}$ - compression chord, $\boxed{B}$ - struts, $\boxed{C}$ - tensile chord, $\boxed{D}$ - shear reinforcement
Figure 6.5: Truss model and notation for shear reinforced members

(2) The angle θ should be limited.

Note: The limiting values of $\cot\theta$ for use in a Country may be found in its National Annex. The recommended limits are given in Expression (6.7N).

$$1 \le \cot\theta \le 2,5 \tag{6.7N}$$

(3) For members with vertical shear reinforcement, the shear resistance, V_{Rd} is the smaller value of:

$$V_{Rd,s} = \frac{A_{sw}}{s} z\, f_{ywd} \cot\theta \qquad (6.8)$$

Note: If Expression (6.10) is used the value of f_{ywd} should be reduced to 0,8 f_{ywk} in Expression (6.8)

and

$$V_{Rd,max} = \alpha_{cw} b_w z\, \nu_1\, f_{cd}/(\cot\theta + \tan\theta) \qquad (6.9)$$

where:
  A_{sw} is the cross-sectional area of the shear reinforcement
  s is the spacing of the stirrups
  f_{ywd} is the design yield strength of the shear reinforcement
  ν_1 is a strength reduction factor for concrete cracked in shear
  α_{cw} is a coefficient taking account of the state of the stress in the compression chord

Note 1: The value of ν_1 and α_{cw} for use in a Country may be found in its National Annex. The recommended value of ν_1 is ν (see Expression (6.6N)).

Note 2: If the design stress of the shear reinforcement is below 80% of the characteristic yield stress f_{yk}, ν_1 may be taken as:
  $\nu_1 = 0,6$ for $f_{ck} \leq 60$ MPa   (6.10.aN)
  $\nu_1 = 0,9 - f_{ck}/200 > 0,5$ for $f_{ck} \geq 60$ MPa   (6.10.bN)

Note 3: The recommended value of α_{cw} is as follows:
  1 for non-prestressed structures
  $(1 + \sigma_{cp}/f_{cd})$ for $0 < \sigma_{cp} \leq 0,25\, f_{cd}$ (6.11.aN)
  $1,25$ for $0,25\, f_{cd} < \sigma_{cp} \leq 0,5\, f_{cd}$ (6.11.bN)
  $2,5\,(1 - \sigma_{cp}/f_{cd})$ for $0,5\, f_{cd} < \sigma_{cp} < 1,0\, f_{cd}$ (6.11.cN)
  where:
    σ_{cp} is the mean compressive stress, measured positive, in the concrete due to the design axial force. This should be obtained by averaging it over the concrete section taking account of the reinforcement. The value of σ_{cp} need not be calculated at a distance less than $0.5d \cot\theta$ from the edge of the support.

Note 4: The maximum effective cross-sectional area of the shear reinforcement, $A_{sw,max}$, for $\cot\theta = 1$ is given by:

$$\frac{A_{sw,max} f_{ywd}}{b_w s} \leq \tfrac{1}{2}\, \alpha_{cw} \nu_1 f_{cd} \qquad (6.12)$$

(4) For members with inclined shear reinforcement, the shear resistance is the smaller value of

$$V_{Rd,s} = \frac{A_{sw}}{s} z f_{ywd} (\cot\theta + \cot\alpha)\sin\alpha \qquad (6.13)$$
and

$$V_{Rd,max} = \alpha_{cw} b_w z \nu_1 f_{cd}(\cot\theta + \cot\alpha)/(1 + \cot^2\theta) \qquad (6.14)$$

Note: The maximum effective shear reinforcement, $A_{sw,max}$ for $\cot\theta = 1$ follows from:

$$\frac{A_{sw,max}\ f_{ywd}}{b_w s} \leq \frac{\tfrac{1}{2}\alpha_{cw} \nu_1 f_{cd}}{\sin\alpha} \qquad (6.15)$$

(5) In regions where there is no discontinuity of V_{Ed} (e.g. for uniformly distributed loading) the shear reinforcement in any length increment $l = z (\cot \theta + \cot \alpha)$ may be calculated using the smallest value of V_{Ed} in the increment.

(6) Where the web contains grouted ducts with a diameter $\phi > b_w/8$ the shear resistance $V_{Rd,max}$ should be calculated on the basis of a nominal web thickness given by:

$$b_{w,nom} = b_w - 0,5\Sigma\phi \qquad (6.16)$$

where ϕ is the outer diameter of the duct and $\Sigma\phi$ is determined for the most unfavourable level.

For grouted metal ducts with $\phi \leq b_w/8$, $b_{w,nom} = b_w$

For non-grouted ducts, grouted plastic ducts and unbonded tendons the nominal web thickness is:

$$b_{w,nom} = b_w - 1,2 \Sigma\phi \qquad (6.17)$$

The value 1,2 in Expression (6.17) is introduced to take account of splitting of the concrete struts due to transverse tension. If adequate transverse reinforcement is provided this value may be reduced to 1,0.

(7) The additional tensile force, ΔF_{td}, in the longitudinal reinforcement due to shear V_{Ed} may be calculated from:

$$\Delta F_{td} = 0,5 \ V_{Ed} (\cot \theta - \cot \alpha) \qquad (6.18)$$

$(M_{Ed}/z) + \Delta F_{td}$ should be taken not greater than $M_{Ed,max}/z$, where $M_{Ed,max}$ is the maximum moment along the beam.

(8) For members with loads applied on the upper side within a distance $0,5d \leq a_v \leq 2,0d$ the contribution of this load to the shear force V_{Ed} may be reduced by $\beta = a_v/2d$.
The shear force V_{Ed}, calculated in this way, should satisfy the condition

$$V_{Ed} \leq A_{sw} \cdot f_{ywd} \sin \alpha \qquad (6.19)$$

where $A_{sw} \cdot f_{ywd}$ is the resistance of the shear reinforcement crossing the inclined shear crack between the loaded areas (see Figure 6.6). Only the shear reinforcement within the central $0,75 \ a_v$ should be taken into account. The reduction by β should only be applied for calculating the shear reinforcement. It is only valid provided that the longitudinal reinforcement is fully anchored at the support.
Figure 6.6: Shear reinforcement in short shear spans with direct strut action

For $a_v < 0,5d$ the value $a_v = 0,5d$ should be used.

The value V_{Ed} calculated without reduction by β, should however always satisfy Expression (6.5).

6.2.4 Shear between web and flanges of T-sections

(1) The shear strength of the flange may be calculated by considering the flange as a system of compressive struts combined with ties in the form of tensile reinforcement.

(2) A minimum amount of longitudinal reinforcement should be provided, as specified in 9.3.1.

(3) The longitudinal shear stress, $v_{Ed,}$ at the junction between one side of a flange and the web is determined by the change of the normal (longitudinal) force in the part of the flange considered, according to:

$$v_{Ed} = \Delta F_d/(h_f \cdot \Delta x) \tag{6.20}$$

where:
    h_f is the thickness of flange at the junctions
    Δx is the length under consideration, see Figure 6.7
    ΔF_d is the change of the normal force in the flange over the length Δx.

$\boxed{A}$ - compressive struts $\boxed{B}$ - longitudinal bar anchored beyond this projected point
(see 6.2.4 (7))

Figure 6.7:   Notations for the connection between flange and web

The maximum value that may be assumed for Δx is half the distance between the section where the moment is 0 and the section where the moment is maximum. Where point loads are applied the length Δx should not exceed the distance between point loads.

(4) The transverse reinforcement per unit length A_{sf}/s_f may be determined as follows:

$$(A_{sf}f_{yd}/s_f) \geq v_{Ed} \cdot h_f/ \cot \theta_f \tag{6.21}$$

To prevent crushing of the compression struts in the flange, the following condition should be satisfied:

$$v_{Ed} \leq v f_{cd} \sin\theta_f \cos\theta_f \tag{6.22}$$

Note: The permitted range of the values for $\cot \theta_f$ for use in a country may be found in its National Annex. The recommended values in the absence of more rigorous calculation are:

$1{,}0 \leq \cot \theta_f \leq 2{,}0$ for compression flanges ($45° \geq \theta_f \geq 26{,}5°$)

$1{,}0 \leq \cot \theta_f \leq 1{,}25$ for tension flanges ($45° \geq \theta_f \geq 38{,}6°$)

(5) In the case of combined shear between the flange and the web, and transverse bending, the area of steel should be the greater than that given by Expression (6.21) or half that given by Expression (6.21) plus that required for transverse bending.

(6) If v_{Ed} is less than or equal to $k f_{ctd}$ no extra reinforcement above that for flexure is required.

Note: The value of k for use in a Country may be found in its National Annex. The recommended value is 0,4.

(7) Longitudinal tension reinforcement in the flange should be anchored beyond the strut required to transmit the force back to the web at the section where this reinforcement is required (See Section (A - A) of Figure 6.7).

6.2.5 Shear at the interface between concrete cast at different times

(1) In addition to the requirements of 6.2.1- 6.2.4 the shear stress at the interface between concrete cast at different times should also satisfy the following:

$$v_{Edi} \leq v_{Rdi} \tag{6.23}$$

v_{Edi} is the design value of the shear stress in the interface and is given by:

$$v_{Edi} = \beta \, V_{Ed} / (z \, b_i) \tag{6.24}$$

where:

β is the ratio of the longitudinal force in the new concrete area and the total longitudinal force either in the compression or tension zone, both calculated for the section considered

V_{Ed} is the transverse shear force

z is the lever arm of composite section

b_i is the width of the interface (see Figure 6.8)

v_{Rdi} is the design shear resistance at the interface and is given by:

$$v_{Rdi} = c \, f_{ctd} + \mu \, \sigma_n + \rho \, f_{yd} (\mu \sin \alpha + \cos \alpha) \leq 0{,}5 \, v \, f_{cd} \tag{6.25}$$

where:

c and μ are factors which depend on the roughness of the interface (see (2))

f_{ctd} is as defined in 3.1.6 (2)P

σ_n stress per unit area caused by the minimum external normal force across the interface that can act simultaneously with the shear force, positive for compression, such that $\sigma_n < 0{,}6 \, f_{cd}$, and negative for tension. When σ_n is tensile $c \, f_{ctd}$ should be taken as 0.

ρ $= A_s / A_i$
Figure 6.8: Examples of interfaces

A_s is the area of reinforcement crossing the interface, including ordinary shear reinforcement (if any), with adequate anchorage at both sides of the interface.

A_i is the area of the joint

α is defined in Figure 6.9, and should be limited by $45° \leq \alpha \leq 90°$

v is a strength reduction factor (see 6.2.2 (6))

A - new concrete,   B - old concrete,   C - anchorage
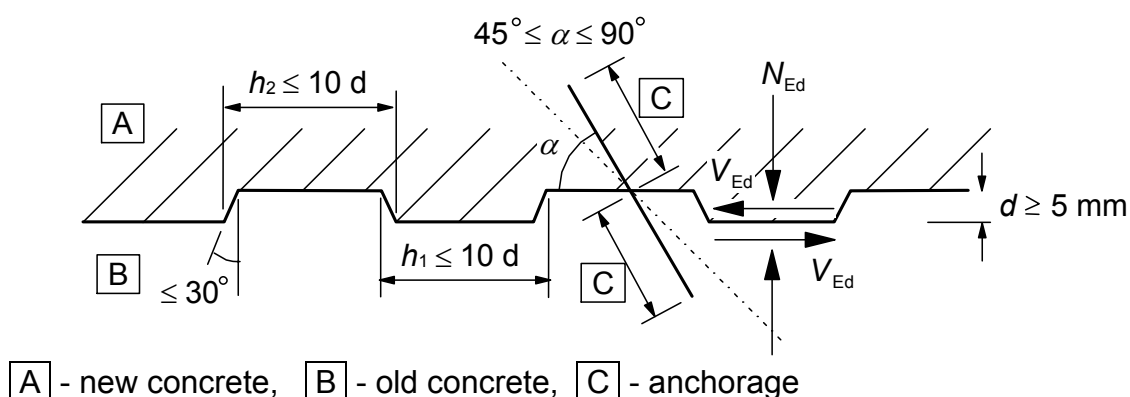

Figure 6.9: Indented construction joint

(2) In the absence of more detailed information surfaces may be classified as very smooth, smooth, rough or indented, with the following examples:

-    Very smooth: a surface cast against steel, plastic or specially prepared wooden moulds: $c = 0,25$ and $\mu = 0,5$
-    Smooth: a slipformed or extruded surface, or a free surface left without further treatment after vibration: $c = 0,35$ and $\mu = 0,6$
-    Rough: a surface with at least 3 mm roughness at about 40 mm spacing, achieved by raking, exposing of aggregate or other methods giving an equivalent behaviour: $c = 0,45$ and $\mu = 0,7$
-    Indented: a surface with indentations complying with Figure 6.9: $c = 0,50$ and $\mu = 0,9$

(3) A stepped distribution of the transverse reinforcement may be used, as indicated in Figure 6.10. Where the connection between the two different concretes is ensured by reinforcement

93

(beams with lattice girders), the steel contribution to v_{Rdi} may be taken as the resultant of the forces taken from each of the diagonals provided that $45° \leq \alpha \leq 135°$.

(4) The longitudinal shear resistance of grouted joints between slab or wall elements may be calculated according to 6.2.5 (1). However in cases where the joint can be significantly cracked, c should be taken as 0 for smooth and rough joints and 0,5 for indented joints (see also 10.9.3 (12)).

(5) Under fatigue or dynamic loads, the values for c in 6.2.5 (1) should be halved.
Figure 6.10: Shear diagram representing the required interface reinforcement

6.3   Torsion

6.3.1   General

(1)P Where the static equilibrium of a structure depends on the torsional resistance of elements of the structure, a full torsional design covering both ultimate and serviceability limit states shall be made.

(2) Where, in statically indeterminate structures, torsion arises from consideration of compatibility only, and the structure is not dependent on the torsional resistance for its stability, then it will normally be unnecessary to consider torsion at the ultimate limit state. In such cases a minimum reinforcement, given in Sections 7.3 and 9.2, in the form of stirrups and longitudinal bars should be provided in order to prevent excessive cracking.

(3) The torsional resistance of a section may be calculated on the basis of a thin-walled closed section, in which equilibrium is satisfied by a closed shear flow. Solid sections may be modelled by equivalent thin-walled sections. Complex shapes, such as T-sections, may be divided into a series of sub-sections, each of which is modelled as an equivalent thin-walled section, and the total torsional resistance taken as the sum of the capacities of the individual elements.

(4) The distribution of the acting torsional moments over the sub-sections should be in proportion to their uncracked torsional stiffnesses. For non-solid sections the equivalent wall thickness should not exceed the actual wall thickness.

(5) Each sub-section may be designed separately.

6.3.2 Design procedure

(1) The shear stress in a wall of a section subject to a pure torsional moment may be calculated from:

$$\tau_{t,i} t_{ef,i} = \frac{T_{Ed}}{2 A_k}$$ (6.26)

The shear force $V_{Ed,i}$ in a wall i due to torsion is given by:

$$V_{Ed,i} = \tau_{t,i} t_{ef,i} z_i$$ (6.27)

where
T_{Ed} is the applied design torsion (see Figure 6.11)

A - centre-line

B - outer edge of effective cross-section, circumference u,

C - cover
Figure 6.11: Notations and definitions used in Section 6.3

A_k is the area enclosed by the centre-lines of the connecting walls, including inner hollow areas.

$\tau_{t,i}$ is the torsional shear stress in wall i

$t_{ef,i}$ is the effective wall thickness. It may be taken as A/u, but should not be taken as less than twice the distance between edge and centre of the longitudinal reinforcement. For hollow sections the real thickness is an upper limit

A is the total area of the cross-section within the outer circumference, including inner hollow areas

u is the outer circumference of the cross-section

z_i is the side length of wall i defined by the distance between the intersection points with the adjacent walls

(2) The effects of torsion and shear for both hollow and solid members may be superimposed, assuming the same value for the strut inclination θ. The limits for θ given in 6.2.3 (2) are also fully applicable for the case of combined shear and torsion.

The maximum bearing capacity of a member loaded in shear and torsion follows from 6.3.2 (4).

(3) The required cross-sectional area of the longitudinal reinforcement for torsion ΣA_{sl} may be calculated from Expression (6.28):

$$\frac{\sum A_{sl} f_{yd}}{u_k} = \frac{T_{Ed}}{2A_k} \cot\theta \qquad\qquad (6.28)$$

where

u_k is the perimeter of the area A_k

f_{yd} is the design yield stress of the longitudinal reinforcement A_{sl}

θ is the angle of compression struts (see Figure 6.5).

In compressive chords, the longitudinal reinforcement may be reduced in proportion to the available compressive force. In tensile chords the longitudinal reinforcement for torsion should be added to the other reinforcement. The longitudinal reinforcement should generally be distributed over the length of side, z_i, but for smaller sections it may be concentrated at the ends of this length.

(4) The maximum resistance of a member subjected to torsion and shear is limited by the capacity of the concrete struts. In order not to exceed this resistance the following condition should be satisfied:

$$T_{Ed} / T_{Rd,max} + V_{Ed} / V_{Rd,max} \leq 1,0 \qquad\qquad (6.29)$$

where:

T_{Ed} is the design torsional moment

V_{Ed} is the design transverse force

$T_{Rd,max}$ is the design torsional resistance moment according to

$$T_{Rd,max} = 2\nu \alpha_{cw} f_{cd} A_k t_{ef,i} \sin\theta \cos\theta \qquad\qquad (6.30)$$

where ν follows from 6.2.2 (6) and α_c from Expression (6.9)

$V_{Rd,max}$ is the maximum design shear resistance according to Expressions (6.9) or (6.14). In solid cross sections the full width of the web may be used to determine $V_{Rd,max}$

(5) For approximately rectangular solid sections only minimum reinforcement is required (see 9.2.1.1) provided that the following condition is satisfied:

$$T_{Ed} / T_{Rd,c} + V_{Ed} / V_{Rd,c} \leq 1,0 \qquad\qquad (6.31)$$

where

$T_{Rd,c}$ is the torsional cracking moment, which may be determined by setting $\tau_{t,i} = f_{ctd}$

$V_{Rd,c}$ follows from Expression (6.2)

6.3.3 Warping torsion

(1) For closed thin-walled sections and solid sections, warping torsion may normally be ignored.

(2) In open thin walled members it may be necessary to consider warping torsion. For very slender cross-sections the calculation should be carried out on the basis of a beam-grid model and for other cases on the basis of a truss model. In all cases the design should be carried out according to the design rules for bending and longitudinal normal force, and for shear.

6.4 Punching

6.4.1 General

(1)P The rules in this Section complement those given in 6.2 and cover punching shear in solid slabs, waffle slabs with solid areas over columns, and foundations.

(2)P Punching shear can result from a concentrated load or reaction acting on a relatively small area, called the loaded area A_{load} of a slab or a foundation.

(3) An appropriate verification model for checking punching failure at the ultimate limit state is shown in Figure 6.12.

θ = arctan (1/2)
    = 26,6°

$\boxed{A}$ - basic control
        section

a) Section

$\boxed{B}$ - basic control area A_{cont}

$\boxed{C}$ - basic control perimeter, u_1

$\boxed{D}$ - loaded area A_{load}

r_{cont} further control perimeter

b) Plan
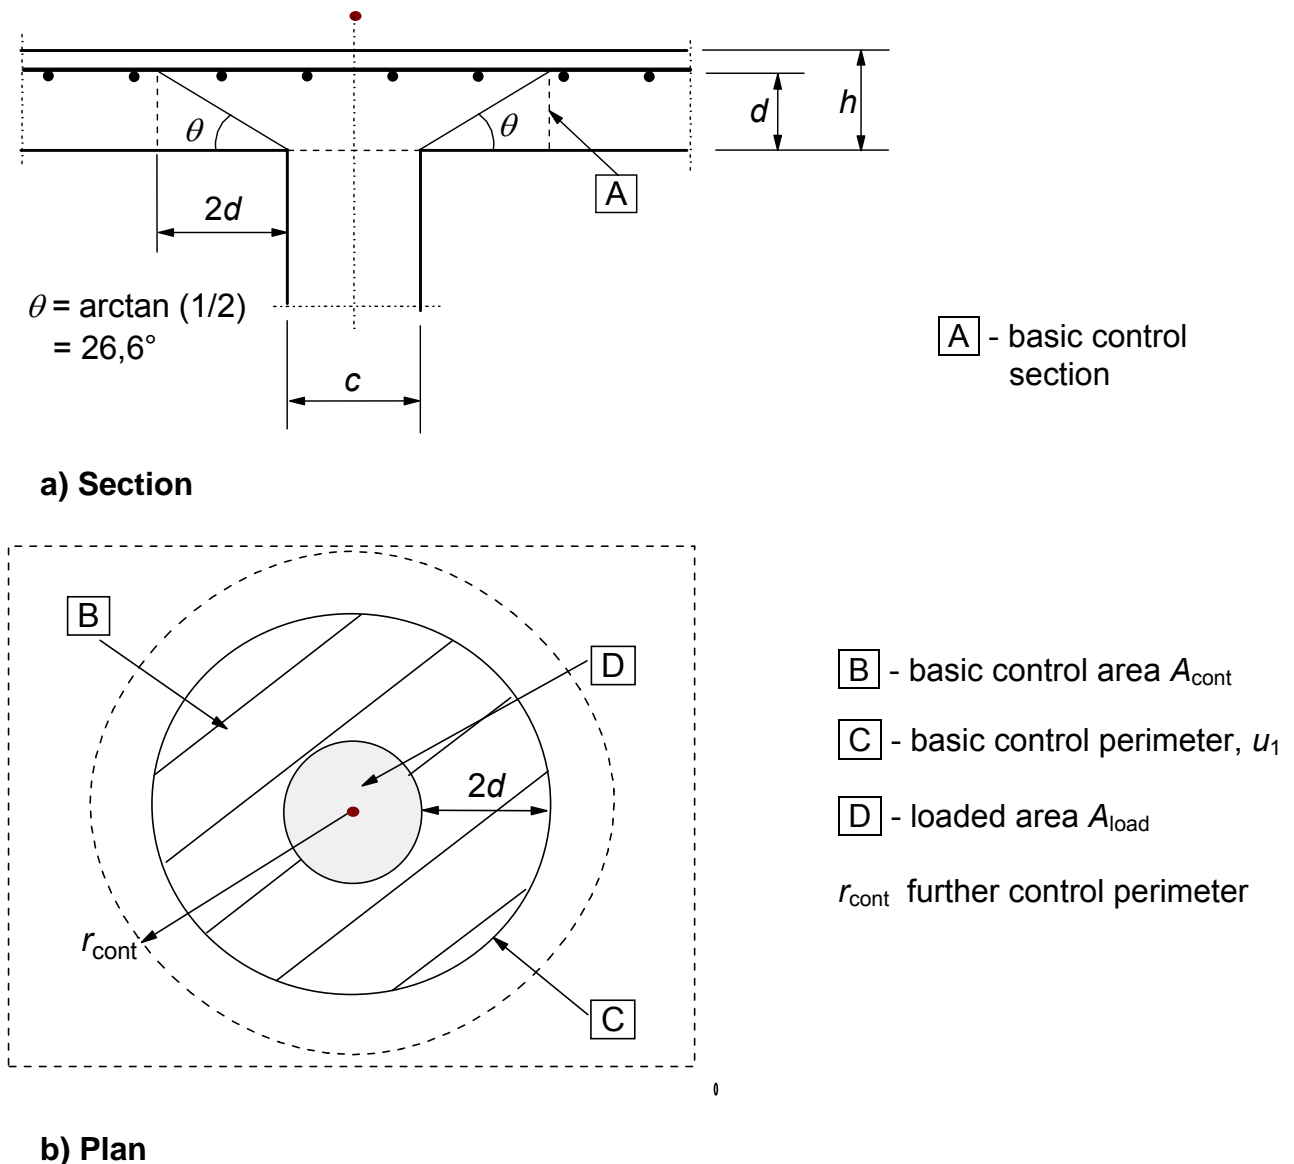

Figure 6.12: Verification model for punching shear at the ultimate limit state

(4) The shear resistance should be checked at the face of the column and at the basic control perimeter u_1. If shear reinforcement is required a further perimeter $u_{out,ef}$ should be found where shear reinforcement is no longer required.

(5) The rules given in 6.4 are principally formulated for the case of uniformly distributed loading. In special cases, such as footings, the load within the control perimeter adds to the resistance of the structural system, and may be subtracted when determining the design punching shear stress.

6.4.2 Load distribution and basic control perimeter

(1) The basic control perimeter u_1 may normally be taken to be at a distance $2,0d$ from the loaded area and should be constructed so as to minimise its length (see Figure 6.13).

The effective depth of the slab is assumed constant and may normally be taken as:

$$d_{eff} = \frac{(d_y + d_z)}{2} \qquad (6.32)$$

where d_y and d_z are the effective depths of the reinforcement in two orthogonal directions.
Figure 6.13: Typical basic control perimeters around loaded areas

(2) Control perimeters at a distance less than $2d$ should be considered where the concentrated force is opposed by a high pressure (e.g. soil pressure on a base), or by the effects of a load or reaction within a distance $2d$ of the periphery of area of application of the force.

(3) For loaded areas situated near openings, if the shortest distance between the perimeter of the loaded area and the edge of the opening does not exceed $6d$, that part of the control perimeter contained between two tangents drawn to the outline of the opening from the centre of the loaded area is considered to be ineffective (see Figure 6.14).
Figure 6.14: Control perimeter near an opening

(4) For a loaded area situated near an edge or a corner, the control perimeter should be taken as shown in Figure 6.15, if this gives a perimeter (excluding the unsupported edges) smaller

than that obtained from (1) and (2) above.
Figure 6.15: Basic control perimeters for loaded areas close to or at edge or corner

(5) For loaded areas situated near an edge or corner, i.e. at a distance smaller than d, special edge reinforcement should always be provided, see 9.3.1.4.

(6) The control section is that which follows the control perimeter and extends over the effective depth d. For slabs of constant depth, the control section is perpendicular to the middle plane of the slab. For slabs or footings of variable depth other than step footings, the effective depth may be assumed to be the depth at the perimeter of the loaded area as shown in Figure 6.16.

A - loaded area

$\theta \geq \arctan (1/2)$
Figure 6.16: Depth of control section in a footing with variable depth

(7) Further perimeters, u_i, inside and outside the basic control area should have the same shape as the basic control perimeter.

(8) For slabs with circular column heads for which $l_H < 2h_H$ (see Figure 6.17) a check of the punching shear stresses according to 6.4.3 is only required on the control section outside the column head. The distance of this section from the centroid of the column r_{cont} may be taken as:

$$r_{cont} = 2d + l_H + 0{,}5c \qquad (6.33)$$

where:
    l_H is the distance from the column face to the edge of the column head
    c is the diameter of a circular column

99
Figure 6.17: Slab with enlarged column head where $l_H < 2,0\ h_H$

For a rectangular column with a rectangular head with $l_H < 2,0 h_H$ (see Figure 6.17) and overall dimensions l_1 and l_2 ($l_1 = c_1 + 2l_{H1}$, $l_2 = c_2 + 2l_{H2}$, $l_1 \le l_2$), the value r_{cont} may be taken as the lesser of:

$$r_{cont} = 2d + 0{,}56 \sqrt{l_1 l_2} \tag{6.34}$$

and

$$r_{cont} = 2d + 0{,}69\ l_1 \tag{6.35}$$

(9) For slabs with enlarged column heads where $l_H > 2h_H$ (see Figure 6.18) control sections both within the head and in the slab should be checked.

(10) The provisions of 6.4.2 and 6.4.3 also apply for checks within the column head with d taken as d_H according to Figure 6.18.

(11) For circular columns the distances from the centroid of the column to the control sections in Figure 6.18 may be taken as:

$$r_{cont,ext} = l_H + 2d + 0{,}5c \tag{6.36}$$

$$r_{cont,int} = 2(d + h_H) + 0{,}5c \tag{6.37}$$
Figure 6.18: Slab with enlarged column head where $l_H > 2(d + h_H)$

100

6.4.3 Punching shear calculation

(1)P The design procedure for punching shear is based on checks at the face of the column and at the basic control perimeter u_1. If shear reinforcement is required a further perimeter $u_{out,ef}$ (see figure 6.22) should be found where shear reinforcement is no longer required. The following design shear stresses (MPa) along the control sections, are defined:

$v_{Rd,c}$ is the design value of the punching shear resistance of a slab without punching shear reinforcement along the control section considered.

$v_{Rd,cs}$ is the design value of the punching shear resistance of a slab with punching shear reinforcement along the control section considered.

$v_{Rd,max}$ is the design value of the maximum punching shear resistance along the control section considered.

(2) The following checks should be carried out:

(a) At the column perimeter, or the perimeter of the loaded area, the maximum punching shear stress should not be exceeded:

$v_{Ed} < v_{Rd,max}$

(b) Punching shear reinforcement is not necessary if:

$v_{Ed} < v_{Rd,c}$

(c) Where v_{Ed} exceeds the value $v_{Rd,c}$ for the control section considered, punching shear reinforcement should be provided according to 6.4.5.

(3) Where the support reaction is eccentric with regard to the control perimeter, the maximum shear stress should be taken as:

$$v_{Ed} = \beta \frac{V_{Ed}}{u_i d} \qquad (6.38)$$

where
   d is the mean effective depth of the slab, which may be taken as $(d_y + d_z)/2$ where:
   d_y, d_z is the effective depths in the y- and z- directions of the control section
   u_i is the length of the control perimeter being considered
   β is given by:

$$\beta = 1 + k \frac{M_{Ed}}{V_{Ed}} \cdot \frac{u_1}{W_1} \qquad (6.39)$$

where
   u_1 is the length of the basic control perimeter
   k is a coefficient dependent on the ratio between the column dimensions c_1 and c_2: its value is a function of the proportions of the unbalanced moment transmitted by uneven shear and by bending and torsion (see Table 6.1).
   W_1 corresponds to a distribution of shear as illustrated in Figure 6.19 and is a function of the basic control perimeter u_1:

$$W_1 = \int_0^{u_i} |e| \, dl \qquad (6.40)$$

101

      dl is a length increment of the perimeter
      e is the distance of dl from the axis about which the moment M_{Ed} acts

Table 6.1: Values of k for rectangular loaded areas

c_1/c_2	$\leq 0,5$	$1,0$	$2,0$	$\geq 3,0$
k	$0,45$	$0,60$	$0,70$	$0,80$
Figure 6.19: Shear distribution due to an unbalanced moment at a slab-internal column connection

For a rectangular column:

$$W_1 = \frac{c_1^2}{2} + c_1 c_2 + 4c_2 d + 16 d^2 + 2\pi d c_1 \tag{6.41}$$

where:
    c_1 is the column dimension parallel to the eccentricity of the load
    c_2 is the column dimension perpendicular to the eccentricity of the load

For internal circular columns β follows from:

$$\beta = 1 + 0,6\pi \frac{e}{D + 4d} \tag{6.42}$$

where D is the diameter of the circular column

For an internal rectangular column where the loading is eccentric to both axes, the following approximate expression for β may be used:

$$\beta = 1 + 1,8 \sqrt{\left(\frac{e_y}{b_z}\right)^2 + \left(\frac{e_z}{b_y}\right)^2} \tag{6.43}$$

where:
    e_y and e_z are the eccentricities M_{Ed}/V_{Ed} along y and z axes respectively
    b_y and b_z is the dimensions of the control perimeter (see Figure 6.13)

Note: e_y results from a moment about the z axis and e_z from a moment about the y axis.

(4) For edge column connections, where the eccentricity perpendicular to the slab edge (resulting from a moment about an axis parallel to the slab edge) is toward the interior and there is no eccentricity parallel to the edge, the punching force may be considered to be uniformly distributed along the control perimeter u_{1*} as shown in Figure 6.20(a).

a) edge column   b) corner column
Figure 6.20: Reduced basic control perimeter u_{1*}

Where there are eccentricities in both orthogonal directions, β may be determined using the following expression:

$$\beta = \frac{u_1}{u_{1*}} + k\,\frac{u_1}{W_1}\,e_{par}$$

(6.44)

where:

u_1 is the basic control perimeter (see Figure 6.15)

u_{1*} is the reduced basic control perimeter (see Figure 6.20(a))

e_{par} is the eccentricity parallel to the slab edge resulting from a moment about an axis perpendicular to the slab edge.

k may be determined from Table 6.1 with the ratio c_1/c_2 replaced by $c_1/2c_2$

W_1 is calculated for the basic control perimeter u_1 (see Figure 6.13).

For a rectangular column as shown in Figure 6.20(a):

$$W_1 = \frac{c_2^2}{4} + c_1 c_2 + 4c_1 d + 8d^2 + \pi d c_2$$

(6.45)

If the eccentricity perpendicular to the slab edge is not toward the interior, Expression (6.39) applies. When calculating W_1 the eccentricity e should be measured from the centroid of the control perimeter.

(5) For corner column connections, where the eccentricity is toward the interior of the slab, it is assumed that the punching force is uniformly distributed along the reduced control perimeter u_{1*}, as defined in Figure 6.20(b). The β-value may then be considered as:

$$\beta = \frac{u_1}{u_{1*}}$$

(6.46)

If the eccentricity is toward the exterior, Expression (6.39) applies.

(6) For structures where the lateral stability does not depend on frame action between the slabs and the columns, and where the adjacent spans do not differ in length by more than 25%, approximate values for β may be used.

Note: Values of β for use in a Country may be found in its National Annex. Recommended values are given in Figure 6.21N.

B

$\beta = 1,4$

A

$\beta = 1,15$
r column

Figure 6.21N: Recommended values for β

(7)   Where a concentrated load is applied close to a flat slab column support the shear force reduction according to 6.2.2 (6) and 6.2.3 (8) respectively is not valid and should not be included.

(8) The punching shear force V_{Ed} in a foundation slab may be reduced due to the favourable action of the soil pressure.

(9) The vertical component V_{pd} resulting from inclined prestressing tendons crossing the control section may be taken into account as a favourable action where relevant.

6.4.4 Punching shear resistance of slabs and column bases without shear reinforcement

(1) The punching shear resistance of a *slab* should be assessed for the basic control section according to 6.4.2. The design punching shear resistance [MPa] may be calculated as follows:

$$v_{Rd,c} = C_{Rd,c} \, k \, (100 \rho_l \, f_{ck})^{1/3} \; + \; k_1 \sigma_{cp} \geq \left(v_{min} + k_1 \sigma_{cp} \right) \qquad (6.47)$$

where:
   f_{ck} is in MPa

$$k = 1 + \sqrt{\frac{200}{d}} \leq 2,0 \quad d \text{ in mm}$$

$$\rho_l = \sqrt{\rho_{ly} \cdot \rho_{lz}} \leq 0,02$$

   ρ_{ly}, ρ_{lz} relate to the bonded tension steel in y- and z- directions respectively. The values ρ_{ly} and ρ_{lz} should be calculated as mean values taking into account a slab width

equal to the column width plus $3d$ each side.

$\sigma_{cp} = (\sigma_{cy} + \sigma_{cz})/2$

where

σ_{cy}, σ_{cz} are the normal concrete stresses in the critical section in y- and z-directions (MPa, positive if compression):

$$\sigma_{c,y} = \frac{N_{Ed,y}}{A_{cy}} \quad \text{and} \quad \sigma_{c,z} = \frac{N_{Ed,z}}{A_{cz}}$$

N_{Edy}, N_{Edz} are the longitudinal forces across the full bay for internal columns and the longitudinal force across the control section for edge columns. The force may be from a load or prestressing action.

A_c is the area of concrete according to the definition of N_{Ed}

Note: The values of $C_{Rd,c}$, v_{min} and k_1 for use in a Country may be found in its National Annex. The recommended value for $C_{Rd,c}$ is $0{,}18/\gamma_c$, for v_{min} is given by Expression (6.3N) and that for k_1 is 0,1.

(2) The punching resistance of column bases should be verified at control perimeters within $2d$ from the periphery of the column.

For concentric loading the net applied force is

$$V_{Ed,red} = V_{Ed} - \Delta V_{Ed} \tag{6.48}$$

where:

V_{Ed} is the applied shear force

ΔV_{Ed} is the net upward force within the control perimeter considered i.e. upward pressure from soil minus self weight of base.

$$v_{Ed} = V_{Ed,red}/ud \tag{6.49}$$

$$v_{Rd} = C_{Rd,c}k(100\,\rho f_{ck})^{1/3} \times 2d/a \geq v_{min} \times \frac{2d}{a} \tag{6.50}$$

where

a is the distance from the periphery of the column to the control perimeter considered

$C_{Rd,c}$ is defined in 6.4.4(1)

v_{min} is defined in 6.4.4(1)

k is defined in 6.4.4(1)

For eccentric loading

$$v_{Ed} = \frac{V_{Ed,red}}{ud}\left[1 + k\frac{M_{Ed}\,u}{V_{Ed,red}W}\right] \tag{6.51}$$

Where k is defined in 6.4.3 (3) or 6.4.3 (4) as appropriate and W is similar to W_1 but for perimeter u.

6.4.5 Punching shear resistance of slabs and column bases with shear reinforcement

(1) Where shear reinforcement is required it should be calculated in accordance with Expression (6.52):

$$v_{Rd,cs} = 0{,}75\,v_{Rd,c} + 1{,}5\,(d/s_r)\,A_{sw}\,f_{ywd,ef}\,(1/(u_1 d))\,\sin\alpha \tag{6.52}$$

where

A_{sw} is the area of one perimeter of shear reinforcement around the column [mm^2]

s_r is the radial spacing of perimeters of shear reinforcement [mm]

$f_{ywd,ef}$ is the effective design strength of the punching shear reinforcement, according to

$f_{ywd,ef}$ = 250 + 0,25 $d \leq f_{ywd}$ [MPa]

d is the mean of the effective depths in the orthogonal directions [mm]

α is the angle between the shear reinforcement and the plane of the slab

If a single line of bent-down bars is provided, then the ratio d/s_r in Expression (6.52) may be given the value 0,67.

(2) Detailing requirements for punching shear reinforcement are given in 9.4.3.

(3) Adjacent to the column the punching shear resistance is limited to a maximum of:

$$v_{Ed} = \frac{\beta V_{Ed}}{u_0 d} \leq v_{Rd,max} \qquad (6.53)$$

where

u_0 for an interior column u_0 = length of column periphery [mm]

for an edge column $u_0 = c_2 + 3d \leq c_2 + 2c_1$ [mm]

for a corner column $u_0 = 3d \leq c_1 + c_2$ [mm]

c_1, c_2 are the column dimensions as shown in Figure 6.20

v see Expression (6.6)

β see 6.4.3 (3), (4) and (5)

Note: The value of $v_{Rd,max}$ for us in a Country may be found in its National Annex. The recommended value is 0,5vf_{cd}.

(4) The control perimeter at which shear reinforcement is not required, u_{out} (or $u_{out,ef}$ see Figure 6.22) should be calculated from Expression (6.54):

$$u_{out,ef} = \beta V_{Ed} / (v_{Rd,c} d) \qquad (6.54)$$

The outermost perimeter of shear reinforcement should be placed at a distance not greater than kd within u_{out} (or $u_{out,ef}$ see Figure 6.22).

A Perimeter u_{out} B Perimeter $u_{out,ef}$
Figure 6.22: Control perimeters at internal columns

Note: The value of k for use in a Country may be found in its National Annex. The recommended value is 1,5.

(5)   Where proprietary products are used as shear reinforcement, $V_{Rd,cs}$ should be determined by testing in accordance with the relevant European Technical Approval. See also 9.4.3.

6.5   Design with strut and tie models

6.5.1   General

(1)P Where a non-linear strain distribution exists (e.g. supports, near concentrated loads or plain stress) strut-and-tie models may be used (see also 5.6.4).

6.5.2   Struts

(1) The design strength for a concrete strut in a region with transverse compressive stress or no transverse stress may be calculated from Expression (6.55) (see Figure 6.23).
Figure 6.23: Design strength of concrete struts without transverse tension

$$\sigma_{Rd,max} = f_{cd} \qquad\qquad (6.55)$$

It may be appropriate to assume a higher design strength in regions where multi-axial compression exists.

(2) The design strength for concrete struts should be reduced in cracked compression zones and, unless a more rigorous approach is used, may be calculated from Expression (6.56) (see Figure 6.24).
Figure 6.24: Design strength of concrete struts with transverse tension

$$\sigma_{Rd,max} = 0,6\,\nu' f_{cd} \qquad\qquad (6.56)$$

Note: The value of ν' for use in a Country may be found in its National Annex. The recommended value is given by equation (6.57N).

$$\nu' = 1 - f_{ck}/250 \qquad\qquad (6.57N)$$

(3) For struts between directly loaded areas, such as corbels or short deep beams, alternative calculation methods are given in 6.2.2 and 6.2.3.

6.5.3 Ties

(1) The design strength of transverse ties and reinforcement should be limited in accordance with 3.2 and 3.3.

(2)   Reinforcement should be adequately anchored in the nodes.

(3) Reinforcement required to resist the forces at the concentrated nodes may be smeared over a length (see Figure 6.25 a) and b)). When the reinforcement in the node area extends over a considerable length of an element, the reinforcement should be distributed over the length where the compression trajectories are curved (ties and struts). The tensile force T may be obtained by:

a) for partial discontinuity regions $\left(b \le \dfrac{H}{2} \right)$, see Figure 6.25 a:

$$T = \frac{1}{4}\frac{b-a}{b}F \tag{6.58}$$

b) for full discontinuity regions $\left(b > \dfrac{H}{2} \right)$, see Figure 6.25 b:

$$T = \frac{1}{4}\left(1 - 0,7\frac{a}{h} \right)F \tag{6.59}$$

$b_{ef} = b$ 　　　　　　　　$b_{ef} = 0,5H + 0,65a; \ a \le h$
a) Partial discontinuity　b) Full discontinuity

Figure 6.25: Parameters for the determination of transverse tensile forces in a compression field with smeared reinforcement

6.5.4 Nodes

(1)P The rules for nodes also apply to regions where concentrated forces are transferred in a member and which are not designed by the strut-and-tie method.

(2)P The forces acting at nodes shall be in equilibrium. Transverse tensile forces perpendicular to an in-plane node shall be considered.

(3) The dimensioning and detailing of concentrated nodes are critical in determining their load-bearing resistance. Concentrated nodes may develop, e.g. where point loads are applied, at supports, in anchorage zones with concentration of reinforcement or prestressing tendons, at bends in reinforcing bars, and at connections and corners of members.

(4) The design values for the compressive stresses within nodes may be determined by:

a) in compression nodes where no ties are anchored at the node (see Figure 6.26)

$$\sigma_{Rd,max} = k_1 \, \nu' f_{cd} \tag{6.60}$$

Note: The value of k_1 for use in a Country may be found in its National Annex. The recommended value is 1,0.

where $\sigma_{Rd,max}$ is the maximum stress which can be applied at the edges of the node. See 6.5.2 (2) for definition of ν'.
Figure 6.26: Compression node without ties

b) in compression - tension nodes with anchored ties provided in one direction (see Figure 6.27),

$$\sigma_{Rd,max} = k_2 \, \nu' \, f_{cd} \tag{6.61}$$

where $\sigma_{Rd,max}$ is the maximum of $\sigma_{Rd,1}$ and $\sigma_{Rd,2}$, See 6.5.2 (2) for definition of ν'.
Figure 6.27: Compression tension node with reinforcement provided in one direction

> **Note:** The value of k_2 for use in a Country may be found in its National Annex. The recommended value is 0,85.

c) in compression - tension nodes with anchored ties provided in more than one direction (see Figure 6.28),
Figure 6.28: Compression tension node with reinforcement provided in two directions

$$\sigma_{Rd,max} = k_3\ \nu'f_{cd} \qquad\qquad (6.62)$$

> **Note:** The value of k_3 for use in a Country may be found in its National Annex. The recommended value is 0,75.

(5) Under the conditions listed below, the design compressive stress values given in 6.5.4 (4) may be increased by up to10% where at least one of the following applies:
- triaxial compression is assured,
- all angles between struts and ties are $\geq 55°$,
- the stresses applied at supports or at point loads are uniform, and the node is confined by stirrups,
- the reinforcement is arranged in multiple layers,
- the node is reliably confined by means of bearing arrangement or friction.

(6) Triaxially compressed nodes may be checked according to Expression (3.24) and (3.25) with $\sigma_{Rd,max} \leq k_4\ \nu'f_{cd}$ if for all three directions of the struts the distribution of load is known.

> **Note:** The value of k_4 for use in a Country may be found in its National Annex. The recommended value is 3,0.

(7) The anchorage of the reinforcement in compression-tension nodes starts at the beginning of the node, e.g. in case of a support anchorage starting at its inner face (see Figure 6.27). The anchorage length should extend over the entire node length. In certain cases, the reinforcement may also be anchored behind the node. For anchorage and bending of reinforcement, see 8.4 to 8.6.

(8) In-plane compression nodes at the junction of three struts may be verified in accordance with Figure 6.26. The maximum average principal node stresses (σ_{c0}, σ_{c1}, σ_{c2}, σ_{c3}) should be checked in accordance with 6.5.4 (4) a). Normally the following may be assumed: $F_{cd,1}/a_1 = F_{cd,2}/a_2 = F_{cd,3}/a_3$ resulting in $\sigma_{cd,1} = \sigma_{cd,2} = \sigma_{cd,3} = \sigma_{cd,0}$.

(9) Nodes at reinforcement bends may be analysed in accordance with Figure 6.28. The average stresses in the struts should be checked in accordance with 6.5.4 (5). The diameter of the mandrel should be checked in accordance with 8.4.

6.6   Anchorages and laps

(1)P The design bond stress is limited to a value depending on the surface characteristics of the reinforcement, the tensile strength of the concrete and confinement of surrounding concrete. This depends on cover, transverse reinforcement and transverse pressure.

(2) The length necessary for developing the required tensile force in an anchorage or lap is calculated on the basis of a constant bond stress.

(3) Application rules for the design and detailing of anchorages and laps are given in 8.4 to 8.8.

6.7   Partially loaded areas

(1)P For partially loaded areas, local crushing (see below) and transverse tension forces (see 6.5) shall be considered.

(2) For a uniform distribution of load on an area A_{c0} (see Figure 6.29) the concentrated resistance force may be determined as follows:

$$F_{Rdu} = A_{c0} \cdot f_{cd} \cdot \sqrt{A_{c1} / A_{c0}} \leq 3{,}0 \cdot f_{cd} \cdot A_{c0} \qquad (6.63)$$

where:
   A_{c0} is the loaded area,
   A_{c1} is the maximum design distribution area with a similar shape to A_{c0}

(3) The design distribution area A_{c1} required for the resistance force F_{Rdu} should correspond to the following conditions:
   - The height for the load distribution in the load direction should correspond to the conditions given in Figure 6.29
   - the centre of the design distribution area A_{c1} should be on the line of action passing through the centre of the load area A_{c0}.
   - If there is more than one compression force acting on the concrete cross section, the designed distribution areas should not overlap.

The value of F_{Rdu} should be reduced if the load is not uniformly distributed on the area A_{c0} or if high shear forces exist.

A - line of action

$h \geq (b_2 - b_1)$ and
$\geq (d_2 - d_1)$
Figure 6.29: Design distribution for partially loaded areas

(4) Reinforcement should be provided for the tensile force due to the effect of the action.

6.8   Fatigue

6.8.1 Verification conditions

(1)P The resistance of structures to fatigue shall be verified in special cases. This verification shall be performed separately for concrete and steel.

(2) A fatigue verification should be carried out for structures and structural components which are subjected to regular load cycles (e.g. crane-rails, bridges exposed to high traffic loads).

6.8.2 Internal forces and stresses for fatigue verification

(1)P The stress calculation shall be based on the assumption of cracked cross sections neglecting the tensile strength of concrete but satisfying compatibility of strains.

(2)P The effect of different bond behaviour of prestressing and reinforcing steel shall be taken into account by increasing the stress range in the reinforcing steel calculated under the assumption of perfect bond by the factor, η, given by

$$\eta = \frac{A_\text{S} + A_\text{P}}{A_\text{S} + A_\text{P} \sqrt{\xi (\phi_\text{S} / \phi_\text{P})}} \qquad\qquad (6.64)$$

where:
   A_s is the area of reinforcing steel
   A_P is the area of prestressing tendon or tendons
   ϕ_S is the largest diameter of reinforcement
   ϕ_P is the diameter or equivalent diameter of prestressing steel
      $\phi_\text{P} = 1,6 \sqrt{A_\text{P}}$ for bundles
      $\phi_\text{P} = 1,75 \, \phi_\text{wire}$ for single 7 wire strands where ϕ_wire is the wire diameter
      $\phi_\text{P} = 1,20 \, \phi_\text{wire}$ for single 3 wire strands where ϕ_wire is the wire diameter
   ξ is the ratio of bond strength between bonded tendons and ribbed steel in concrete. The value is subject to the relevant European Technical Approval. In the absence of this the values given in Table 6.2 may be used.

Table 6.2: Ratio of bond strength, ξ, between tendons and reinforcing steel

prestressing steel	ξ		
	pre-tensioned	bonded, post-tensioned	
		$\leq$ C50/60	$\geq$ C70/85
smooth bars and wires	Not applicable	0,3	0,15
strands	0,6	0,5	0,25
indented wires	0,7	0,6	0,3
ribbed bars	0,8	0,7	0,35
Note: For intermediate values between C50/60 and C70/85 interpolation may be used.			

(3) In the design of the shear reinforcement the inclination of the compressive struts θ_{fat} may be calculated using a strut and tie model or in accordance with Expression (6.65).

$$\tan\theta_{fat} = \sqrt{\tan\theta} \leq 1{,}0 \qquad\qquad (6.65)$$

where:
  θ is the angle of concrete compression struts to the beam axis assumed in ULS design (see 6.2.3)

6.8.3 Combination of actions

(1)P   For the calculation of the stress ranges the action shall be divided into non-cycling and fatigue-inducing cyclic actions (a number of repeated actions of load).

(2)P The basic combination of the non-cyclic load is similar to the definition of the frequent combination for SLS:

$$E_d = E\{G_{k,j};P;\psi_{1,1}Q_{k,1};\psi_{2,i}Q_{k,i}\}\; j \geq 1;\; i > 1 \qquad\qquad (6.66)$$

The combination of actions in bracket { }, (called the basic combination), may be expressed as:

$$\sum_{j\geq1}G_{k,j}\;''+''\; P \;''+''\; \psi_{1,1}Q_{k,1}\;''+''\; \sum_{i>1}\psi_{2,i}Q_{k,i} \qquad\qquad (6.67)$$

  Note: $Q_{k,1}$ and $Q_{k,l}$ are non-cyclic, non-permanent actions

(3)P The cyclic action shall be combined with the unfavourable basic combination:

$$E_d = E\{\{G_{k,j};P;\psi_{1,1}Q_{k,1};\psi_{2,i}Q_{k,i}\}\;;Q_{fat}\}\;\; j \geq 1;\;\; i > 1 \qquad\qquad (6.68)$$

The combination of actions in bracket { }, (called the basic combination plus the cyclic action), can be expressed as:

$$\left(\sum_{j\geq1}G_{k,j}''+'' P ''+'' \psi_{1,1}Q_{k,1} ''+'' \sum_{i>1}\psi_{2,i}Q_{k,i}\right)''+'' Q_{fat} \qquad\qquad (6.69)$$

where:
  Q_{fat} is the relevant fatigue load (e.g. traffic load as defined in EN 1991 or other cyclic load)

6.8.4 Verification procedure for reinforcing and prestressing steel

(1) The damage of a single stress amplitude $\Delta\sigma$ may be determined by using the corresponding S-N curves (Figure 6.30) for reinforcing and prestressing steel. The applied load should be multiplied by $\gamma_{F,fat}$. The resisting stress range at N^* cycles $\Delta\sigma_{Rsk}$ obtained should be divided by the safety factor $\gamma_{S,fat}$.

  Note 1: The values of $\gamma_{F,fat}$ for use in a Country may be found in its National Annex. The recommended value is 1,0.
Figure 6.30: Shape of the characteristic fatigue strength curve (S-N-curves for reinforcing and prestressing steel)

Note 2: The values of parameters for reinforcing steels and prestressing steels S-N curves for use in a Country may be found in its National Annex. The recommended values are given in Table 6.3N and 6.4N which apply for reinforcing and prestressing steel respectively.

Table 6.3N: Parameters for S-N curves for reinforcing steel

Type of reinforcement		stress exponent		$\Delta\sigma_{Rsk}$ (MPa)
	N^*	k_1	k_2	at N^* cycles
Straight and bent bars[1]	10^6	5	9	162,5
Welded bars and wire fabrics	10^7	3	5	58,5
Splicing devices	10^7	3	5	35

Note 1: Values for $\Delta\sigma_{Rsk}$ are those for straight bars. Values for bent bars should be obtained using a reduction factor $\zeta = 0,35 + 0,026\ D/\phi$.

where:
 D diameter of the mandrel
 ϕ bar diameter

Table 6.4N: Parameters for S-N curves of prestressing steel

S-N curve of prestressing steel used for		stress exponent		$\Delta\sigma_{Rsk}$ (MPa)
	N^*	k_1	k_2	at N^* cycles
pre-tensioning	10^6	5	9	185
post-tensioning				
– single strands in plastic ducts	10^6	5	9	185
– straight tendons or curved tendons in plastic ducts	10^6	5	10	150
– curved tendons in steel ducts	10^6	5	7	120
– splicing devices	10^6	5	5	80

(2) For multiple cycles with variable amplitudes the damage may be added by using the Palmgren-Miner Rule. Hence, the fatigue damage factor D_{Ed} of steel caused by the relevant fatigue loads should satisfy the condition:

$$D_{Ed} = \sum_i \frac{n(\Delta\sigma_i)}{N(\Delta\sigma_i)} < 1 \qquad (6.70)$$

where:

$n(\Delta\sigma_i)$ is the applied number of cycles for a stress range $\Delta\sigma_i$

$N(\Delta\sigma_i)$ is the resisting number of cycles for a stress range $\Delta\sigma_i$

(3)P If prestressing or reinforcing steel is exposed to fatigue loads, the calculated stresses shall not exceed the design yield strength of the steel.

(4) The yield strength should be verified by tensile tests for the steel used.

(5) When the rules of 6.8 are used to evaluate the remaining life of existing structures, or to assess the need for strengthening, once corrosion has started the stress range may be determined by reducing the stress exponent k_2 for straight and bent bars.

> **Note:** The value of k_2 for use in a Country may be found in its National Annex. The recommended values is 5.

(6)P The stress range of welded bars shall never exceed the stress range of straight and bent bars.

6.8.5 Verification using damage equivalent stress range

(1) Instead of an explicit verification of the damage strength according to 6.8.4 the fatigue verification of standard cases with known loads (railway and road bridges) may also be performed as follows:

– by damage equivalent stress ranges for steel according to 6.8.5 (3)
– damage equivalent compression stresses for concrete according to 6.8.7

(2) The method of damage equivalent stress range consists of representing the actual operational loading by N^* cycles of a single stress range. EN 1992-2 gives relevant fatigue loading models and procedures for the calculation of the equivalent stress range $\Delta\sigma_{S,equ}$ for superstructures of road and railway bridges.

(3) For reinforcing or prestressing steel and splicing devices adequate fatigue resistance should be assumed if the Expression (6.71) is satisfied:

$$\gamma_{F,fat} \cdot \Delta\sigma_{S,equ}\left(N^*\right) \le \frac{\Delta\sigma_{Rsk}\left(N^*\right)}{\gamma_{s,fat}} \qquad (6.71)$$

where:

$\Delta\sigma_{Rsk}(N^*)$ is the stress range at N^* cycles from the appropriate S-N curves given in Figure 6.30.

Note: See also Tables 6.3N and 6.4N.

$\Delta\sigma_{S,equ}(N^*)$ is the damage equivalent stress range for different types of reinforcement and considering the number of loading cycles N^*. For building construction $\Delta\sigma_{S,equ}(N^*)$ may be approximated by $\Delta\sigma_{S,max}$.

$\Delta\sigma_{S,max}$ is the maximum steel stress range under the relevant load combinations

6.8.6 Other verifications

(1) Adequate fatigue resistance may be assumed for unwelded reinforcing bars under tension, if the stress range under frequent cyclic load combined with the basic combination is $\Delta\sigma_S \leq k_1$.

> **Note:** The value of k_1 for use in a Country may be found in its National Annex. The recommended value is 70MPa.

For welded reinforcing bars under tension adequate fatigue resistance may be assumed if the stress range under frequent load combined with the basic combination is $\Delta\sigma_S \leq k_2$.

> **Note:** The value of k_2 for use in a Country may be found in its National Annex. The recommended value is 35MPa.

(2) As a simplification to (1) above verification may be carried out using the Frequent load combination. If this is satisfied then no further checks are necessary.

(3) Where welded joints or splicing devices are used in prestressed concrete, no tension should exist in the concrete section within 200 mm of the prestressing tendons or reinforcing steel under the frequent load combination together with a reduction factor of k_3 for the mean value of prestressing force, P_m,

> **Note:** The value of k_3 for use in a Country may be found in its National Annex. The recommended value is 0,9.

6.8.7 Verification of concrete under compression or shear

(1) A satisfactory fatigue resistance may be assumed for concrete under compression, if the following condition is fulfilled:

$$E_{cd,\max,equ} + 0,43\sqrt{1-R_{equ}} \leq 1 \qquad (6.72)$$

where:

$$R_{equ} = \frac{E_{cd,min,equ}}{E_{cd,max,equ}} \qquad (6.73)$$

$$E_{cd,min,equ} = \frac{\sigma_{cd,min,equ}}{f_{cd,fat}} \qquad (6.74)$$

$$E_{cd,max,equ} = \frac{\sigma_{cd,max,equ}}{f_{cd,fat}} \qquad (6.75)$$

where :

R_{equ} is the stress ratio

$E_{cd,min,equ}$ is the minimum compressive stress level

$E_{cd,max,equ}$ is the maximum compressive stress level

$f_{cd,fat}$ is the design fatigue strength of concrete according to (6.76)

$\sigma_{cd,max,equ}$ is the upper stress of the ultimate amplitude for N cycles

$\sigma_{cd,min,equ}$ is the lower stress of the ultimate amplitude for N cycles

> **Note:** The value of N ($\leq 10^6$ cycles) for use in a Country may be found in its National Annex. The recommended value is $N = 10^6$ cycles.

$$f_{cd,fat} = k_1 \beta_{cc}(t_0) f_{cd} \left(1 - \frac{f_{ck}}{250}\right)$$

(6.76)

where:

$\beta_{cc}(t_0)$ is a coefficient for concrete strength at first load application (see 3.1.2 (6))

t_0 is the time of the start of the cyclic loading on concrete in days

Note: The value of k_1 for use in a Country may be found in its National Annex. The recommended value for N = 10^6 cycles is 0,85.

(2) The fatigue verification for concrete under compression may be assumed, if the following condition is satisfied:

$$\frac{\sigma_{c,max}}{f_{cd,fat}} \leq 0,5 + 0,45 \frac{\sigma_{c,min}}{f_{cd,fat}}$$

(6.77)

$\leq 0,9$ for $f_{ck} \leq 50$ MPa

$\leq 0,8$ for $f_{ck} > 50$ MPa

where:

$\sigma_{c,max}$ is the maximum compressive stress at a fibre under the frequent load combination (compression measured positive)

$\sigma_{c,min}$ is the minimum compressive stress at the same fibre where $\sigma_{c,max}$ occurs. If $\sigma_{c,min}$ is a tensile stress, then $\sigma_{c,min}$ should be taken as 0.

(3) Expression (6.77) also applies to the compression struts of members subjected to shear. In this case the concrete strength $f_{cd,fat}$ should be reduced by the strength reduction factor (see 6.2.2 (6)).

(4) For members not requiring design shear reinforcement for the ultimate limit state it may be assumed that the concrete resists fatigue due to shear effects where the following apply:

- for $\dfrac{V_{Ed,min}}{V_{Ed,max}} \geq 0$:

$$\frac{|V_{Ed,max}|}{|V_{Rd,c}|} \leq 0,5 + 0,45 \frac{|V_{Ed,min}|}{|V_{Rd,c}|} \begin{cases} \leq 0,9 \ \text{up to} \ C50/60 \\ \leq 0,8 \ \text{greater than} \ C55/67 \end{cases}$$

(6.78)

- for $\dfrac{V_{Ed,min}}{V_{Ed,max}} < 0$:

$$\frac{|V_{Ed,max}|}{|V_{Rd,c}|} \leq 0,5 - \frac{|V_{Ed,min}|}{|V_{Rd,c}|}$$

(6.79)

where:

$V_{Ed,max}$ is the design value of the maximum applied shear force under frequent load combination

$V_{Ed,min}$ is the design value of the minimum applied shear force under frequent load combination in the cross-section where $V_{Ed,max}$ occurs

$V_{Rd,c}$ is the design value for shear-resistance according to Expression (6.2.a).

SECTION 7   SERVICEABILITY LIMIT STATES (SLS)

7.1   General

(1)P This section covers the common serviceability limit states. These are:

-   stress limitation (see 7.2)

-   crack control (see 7.3)

-   deflection control (see 7.4)

Other limit states (such as vibration) may be of importance in particular structures but are not covered in this Standard.

(2) In the calculation of stresses and deflections, cross-sections should be assumed to be uncracked provided that the flexural tensile stress does not exceed $f_{ct,eff}$. The value of $f_{ct,eff}$ may be taken as f_{ctm} or $f_{ctm,fl}$ provided that the calculation for minimum tension reinforcement is also based on the same value. For the purposes of calculating crack widths and tension stiffening f_{ctm} should be used.

7.2   Stress limitation

(1)P The compressive stress in the concrete shall be limited in order to avoid longitudinal cracks, micro-cracks or high levels of creep, where they could result in unacceptable effects on the function of the structure.

(2) Longitudinal cracks may occur if the stress level under the characteristic combination of loads exceeds a critical value. Such cracking may lead to a reduction of durability. In the absence of other measures, such as an increase in the cover to reinforcement in the compressive zone or confinement by transverse reinforcement, it may be appropriate to limit the compressive stress to a value $k_1 f_{ck}$ in areas exposed to environments of exposure classes XD, XF and XS (see Table 4.1).

> **Note:** The value of k_1 for use in a Country may be found in its National Annex. The recommended value is 0,6.

(3) If the stress in the concrete under the quasi-permanent loads is less than $k_2 f_{ck}$, linear creep may be assumed. If the stress in concrete exceeds $k_2 f_{ck}$, non-linear creep should be considered (see 3.1.4)

> **Note:** The value of k_2 for use in a Country may be found in its National Annex. The recommended value is 0,45.

(4)P Tensile stresses in the reinforcement shall be limited in order to avoid inelastic strain, unacceptable cracking or deformation.

(5) Unacceptable cracking or deformation may be assumed to be avoided if, under the characteristic combination of loads, the tensile stress in the reinforcement does not exceed $k_3 f_{yk}$. Where the stress is caused by an imposed deformation, the tensile stress should not exceed $k_4 f_{yk}$. The mean value of the stress in prestressing tendons should not exceed $k_5 f_{pk}$

> **Note:** The values of k_3, k_4 and k_5 for use in a Country may be found in its National Annex. The recommended values are 0,8, 1 and 0,75 respectively.

7.3   Crack control

7.3.1   General considerations

(1)P Cracking shall be limited to an extent that will not impair the proper functioning or durability of the structure or cause its appearance to be unacceptable.

(2) Cracking is normal in reinforced concrete structures subject to bending, shear, torsion or tension resulting from either direct loading or restraint or imposed deformations.

(3) Cracks may also arise from other causes such as plastic shrinkage or expansive chemical reactions within the hardened concrete. Such cracks may be unacceptably large but their avoidance and control lie outside the scope of this Section.

(4) Cracks may be permitted to form without any attempt to control their width, provided they do not impair the functioning of the structure.

(5) A limiting calculated crack width, w_{max}, taking into account the proposed function and nature of the structure and the costs of limiting cracking, should be established.

> **Note:** The value of w_{max} for use in a Country may be found in its National Annex. The recommended values for relevant exposure classes are given in Table 7.1N.

Table 7.1N Recommended values of w_{max} (mm)

Exposure Class	Reinforced members and prestressed members with unbonded tendons	Prestressed members with bonded tendons
	Quasi-permanent load combination	Frequent load combination
X0, XC1	0,4[1]	0,2
XC2, XC3, XC4	0,3	0,2[2]
XD1, XD2, XS1, XS2, XS3		Decompression

Note 1: For X0, XC1 exposure classes, crack width has no influence on durability and this limit is set to guarantee acceptable appearance. In the absence of appearance conditions this limit may be relaxed.
Note 2: For these exposure classes, in addition, decompression should be checked under the quasi-permanent combination of loads.

> In the absence of specific requirements (e.g. water-tightness), it may be assumed that limiting the calculated crack widths to the values of w_{max} given in Table 7.1N, under the quasi-permanent combination of loads, will generally be satisfactory for reinforced concrete members in buildings with respect to appearance and durability.
> The durability of prestressed members may be more critically affected by cracking. In the absence of more detailed requirements, it may be assumed that limiting the calculated crack widths to the values of w_{max} given in Table 7.1N, under the frequent combination of loads, will generally be satisfactory for prestressed concrete members. The decompression limit requires that all parts of the bonded tendons or duct lie at least 25 mm within concrete in compression.

(6) For members with only unbonded tendons, the requirements for reinforced concrete elements apply. For members with a combination of bonded and unbonded tendons requirements for prestressed concrete members with bonded tendons apply.

(7) Special measures may be necessary for members subjected to exposure class XD3. The choice of appropriate measures will depend upon the nature of the aggressive agent involved.

(8) When using strut-and-tie models with the struts oriented according to the compressive stress trajectories in the uncracked state, it is possible to use the forces in the ties to obtain the corresponding steel stresses to estimate the crack width (see 5.6.4 (2).

(9) Crack widths may be calculated according to 7.3.4. A simplified alternative is to limit the bar size or spacing according to 7.3.3.

7.3.2 Minimum reinforcement areas

(1)P If crack control is required, a minimum amount of bonded reinforcement is required to control cracking in areas where tension is expected. The amount may be estimated from equilibrium between the tensile force in concrete just before cracking and the tensile force in reinforcement at yielding or at a lower stress if necessary to limit the crack width.

(2)   Unless a more rigorous calculation shows lesser areas to be adequate, the required minimum areas of reinforcement may be calculated as follows. In profiled cross sections like T-beams and box girders, minimum reinforcement should be determined for the individual parts of the section (webs, flanges).

$$A_{s,min}\sigma_s = k_c \, k \, f_{ct,eff} \, A_{ct} \qquad\qquad (7.1)$$

where:

$A_{s,min}$ is the minimum area of reinforcing steel within the tensile zone

A_{ct} is the area of concrete within tensile zone. The tensile zone is that part of the section which is calculated to be in tension just before formation of the first crack

σ_s is the absolute value of the maximum stress permitted in the reinforcement immediately after formation of the crack. This may be taken as the yield strength of the reinforcement, f_{yk}. A lower value may, however, be needed to satisfy the crack width limits according to the maximum bar size or spacing (see 7.3.3 (2))

$f_{ct,eff}$ is the mean value of the tensile strength of the concrete effective at the time when the cracks may first be expected to occur:

$f_{ct,eff} = f_{ctm}$ or lower, ($f_{ctm}(t)$), if cracking is expected earlier than 28 days

k is the coefficient which allows for the effect of non-uniform self-equilibrating stresses, which lead to a reduction of restraint forces

= 1,0 for webs with $h \le 300$ mm or flanges with widths less than 300 mm

= 0,65 for webs with $h \ge 800$ mm or flanges with widths greater than 800 mm intermediate values may be interpolated

k_c is a coefficient which takes account of the stress distribution within the section immediately prior to cracking and of the change of the lever arm:

For pure tension $k_c = 1,0$

For bending or bending combined with axial forces:
- For rectangular sections and webs of box sections and T-sections:

$$k_c = 0,4 \cdot \left[1 - \frac{\sigma_c}{k_1(h/h^*)f_{ct,eff}} \right] \le 1 \qquad\qquad (7.2)$$

- For flanges of box sections and T-sections:

$$k_c = 0.9 \frac{F_{cr}}{A_{ct} f_{ct,eff}} \geq 0.5 \qquad (7.3)$$

where

σ_c is the mean stress of the concrete acting on the part of the section under consideration:

$$\sigma_c = \frac{N_{Ed}}{bh} \qquad (7.4)$$

N_{Ed} is the axial force at the serviceability limit state acting on the part of the cross-section under consideration (compressive force positive). N_{Ed} should be determined considering the characteristic values of prestress and axial forces under the relevant combination of actions

h^* $h^* = h$ for $h < 1.0$ m

          $h^* = 1.0$ m   for $h \geq 1.0$ m

k_1 is a coefficient considering the effects of axial forces on the stress distribution:

       $k_1 = 1.5$ if N_{Ed} is a compressive force

       $k_1 = \dfrac{2h^*}{3h}$ if N_{Ed} is a tensile force

F_{cr} is the absolute value of the tensile force within the flange immediately prior to cracking due to the cracking moment calculated with $f_{ct,eff}$

(3) Bonded tendons in the tension zone may be assumed to contribute to crack control within a distance ≤ 150 mm from the centre of the tendon. This may be taken into account by adding the term $\xi_1 A_p{}' \Delta\sigma_p$ to the left hand side of Expression (7.1),

    where

      $A_p{}'$ is the area of pre or post-tensioned tendons within $A_{c,eff}$.

      $A_{c,eff}$ is the effective area of concrete in tension surrounding the reinforcement or prestressing tendons of depth, $h_{c,ef}$, where $h_{c,ef}$ is the lesser of $2.5(h-d)$, $(h-x)/3$ or $h/2$ (see Figure 7.1).

      ξ_1 is the adjusted ratio of bond strength taking into account the different diameters of prestressing and reinforcing steel:

$$= \sqrt{\xi \cdot \frac{\phi_s}{\phi_p}} \qquad (7.5)$$

      ξ ratio of bond strength of prestressing and reinforcing steel, according to Table 6.2 in 6.8.2.

      ϕ_s largest bar diameter of reinforcing steel

      ϕ_p equivalent diameter of tendon according to 6.8.2

      If only prestressing steel is used to control cracking, $\xi_1 = \sqrt{\xi \cdot}$.

    $\Delta\sigma_p$ Stress variation in prestressing tendons from the state of zero strain of the concrete at the same level

(4) In prestressed members no minimum reinforcement is required in sections where, under the characteristic combination of loads and the characteristic value of prestress, the concrete is compressed or the absolute value of the tensile stress in the concrete is below $\sigma_{ct,p}$.

    Note: The value of $\sigma_{ct,p}$ for use in a Country may be found in its National Annex. The recommended value is $f_{ct,eff}$ in accordance with 7.3.2 (2).

A - level of steel centroid

B - effective tension area, $A_{c,eff}$

a) Beam

B - effective tension area, $A_{c,eff}$

b) Slab

B - effective tension area for upper surface, $A_{ct,eff}$

C - effective tension area for lower surface, $A_{cb,eff}$

c) Member in tension
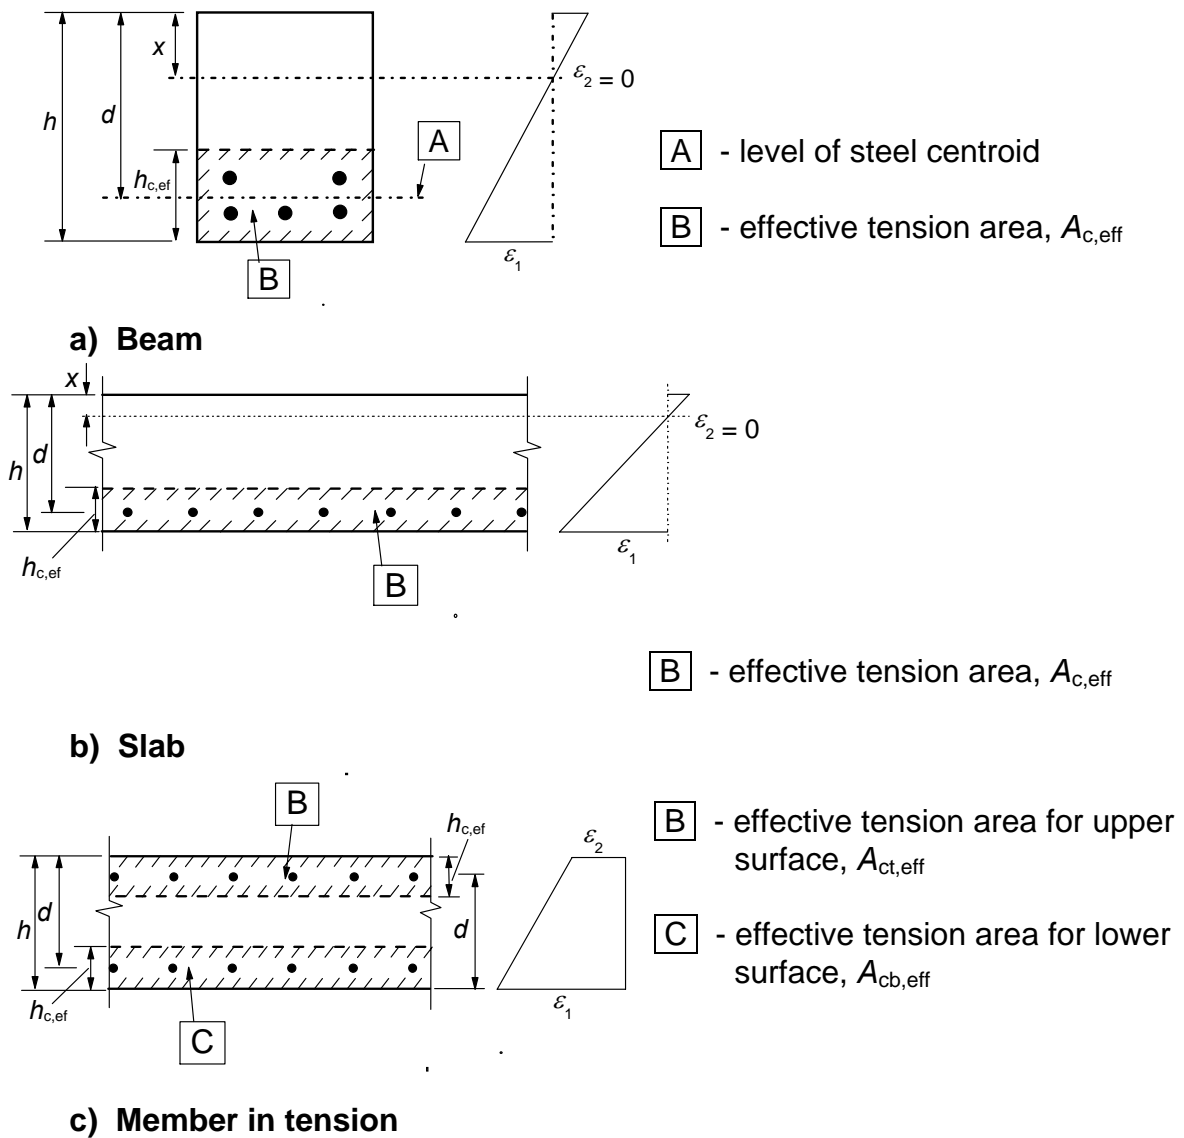

Figure 7.1: Effective tension area (typical cases)

7.3.3 Control of cracking without direct calculation

(1) For reinforced or prestressed slabs in buildings subjected to bending without significant axial tension, specific measures to control cracking are not necessary where the overall depth does not exceed 200 mm and the provisions of 9.3 have been applied.

(2) The rules given in 7.3.4 may be presented in a tabular form by restricting the bar diameter or spacing as a simplification.

Note: Where the minimum reinforcement given by 7.3.2 is provided, crack widths are unlikely to be excessive if:
- for cracking caused dominantly by restraint, the bar sizes given in Table 7.2N are not exceeded where the steel stress is the value obtained immediately after cracking (i.e. σ_s in Expression (7.1)).
- for cracks caused mainly by loading, either the provisions of Table 7.2N or the provisions of Table 7.3N are complied with. The steel stress should be calculated on the basis of a cracked section under the relevant combination of actions.

For pre-tensioned concrete, where crack control is mainly provided by tendons with direct bond, Tables 7.2N and 7.3N may be used with a stress equal to the total stress minus prestress. For post-tensioned concrete, where crack control is provided mainly by ordinary reinforcement, the tables may be used with the stress in this reinforcement calculated with the effect of prestressing forces included.

Table 7.2N Maximum bar diameters ϕ_s^* for crack control[1]

Steel stress[2] [MPa]	Maximum bar size [mm]		
	w_k= 0,4 mm	w_k= 0,3 mm	w_k= 0,2 mm
160	40	32	25
200	32	25	16
240	20	16	12
280	16	12	8
320	12	10	6
360	10	8	5
400	8	6	4
450	6	5	-

Notes: 1. The values in the table are based on the following assumptions:
c = 25mm; $f_{ct,eff}$ = 2,9MPa; h_{cr} = 0,5; (h-d) = 0,1h; k_1 = 0,8; k_2 = 0,5; k_c = 0,4; k = 1,0; k_t = 0,4 and k' = 1,0
2. Under the relevant combinations of actions

Table 7.3N Maximum bar spacing for crack control[1]

Steel stress[2] [MPa]	Maximum bar spacing [mm]		
	w_k=0,4 mm	w_k=0,3 mm	w_k=0,2 mm
160	300	300	200
200	300	250	150
240	250	200	100
280	200	150	50
320	150	100	-
360	100	50	-

For Notes see Table 7.2N

The maximum bar diameter should be modified as follows:

Bending (at least part of section in compression):

$$\phi_s = \phi_s^* \, (f_{ct,eff}/2,9) \, \frac{k_c h_{cr}}{2 \, (\, h\text{-}d \,)} \qquad\qquad (7.6N)$$

Tension (uniform axial tension)

$$\phi_s = \phi_s^*(f_{ct,eff}/2,9)h_{cr}/(8(h\text{-}d)) \qquad\qquad (7.7N)$$

where:
- ϕ_s is the adjusted maximum bar diameter
- ϕ_s^* is the maximum bar size given in the Table 7.2N
- h is the overall depth of the section
- h_{cr} is the depth of the tensile zone immediately prior to cracking, considering the characteristic values of prestress and axial forces under the quasi-permanent combination of actions
- d is the effective depth to the centroid of the outer layer of reinforcement

Where all the section is under tension h - d is the minimum distance from the centroid of the layer of reinforcement to the face of the concrete (consider each face where the bar is not placed symmetrically).

(3) Beams with a total depth of 1000 mm or more, where the main reinforcement is concentrated in only a small proportion of the depth, should be provided with additional skin reinforcement to control cracking on the side faces of the beam. This reinforcement should be evenly distributed between the level of the tension steel and the neutral axis and should be located within the links. The area of the skin reinforcement should not be less than the amount obtained from 7.3.2 (2) taking k as 0,5 and σ_s as f_{yk}. The spacing and size of suitable bars may be obtained from 7.3.4 or a suitable simplification (see 7.3.3 (2)) assuming pure tension and a steel stress of half the value assessed for the main tension reinforcement.

(4) It should be noted that there are particular risks of large cracks occurring in sections where there are sudden changes of stress, e.g.
- at changes of section
- near concentrated loads
- positions where bars are curtailed
- areas of high bond stress, particularly at the ends of laps

Care should be taken at such areas to minimise the stress changes wherever possible. However, the rules for crack control given above will normally ensure adequate control at these points provided that the rules for detailing reinforcement given in Sections 8 and 9 are applied.

(5) Cracking due to tangential action effects may be assumed to be adequately controlled if the detailing rules given in 9.2.2, 9.2.3, 9.3.2 and 9.4.4.3 are observed.

7.3.4 Calculation of crack widths

(1)   The crack width, w_k, may be calculated from Expression (7.8):

$$w_k = s_{r,max} (\varepsilon_{sm} - \varepsilon_{cm}) \qquad (7.8)$$

where

$s_{r,max}$ is the maximum crack spacing

ε_{sm} is the mean strain in the reinforcement under the relevant combination of loads, including the effect of imposed deformations and taking into account the effects of tension stiffening. Only the additional tensile strain beyond the state of zero strain of the concrete at the same level is considered

ε_{cm} is the mean strain in the concrete between cracks

(2) $\varepsilon_{sm} - \varepsilon_{cm}$ may be calculated from the expression:

$$\varepsilon_{sm} - \varepsilon_{cm} = \frac{\sigma_s - k_t \dfrac{f_{ct,eff}}{\rho_{p,eff}} \left(1 + \alpha_e \rho_{p,eff}\right)}{E_s} \geq 0,6 \frac{\sigma_s}{E_s} \qquad (7.9)$$

where:

σ_s is the stress in the tension reinforcement assuming a cracked section. For pretensioned members, σ_s may be replaced by $\Delta\sigma_p$ the stress variation in prestressing tendons from the state of zero strain of the concrete at the same level.

α_e is the ratio E_s/E_{cm}

$\rho_{p,eff}$ $(A_s + \xi_1{}^2 A_p')/A_{c,eff} \qquad (7.10)$

A_p' and $A_{c,eff}$ are as defined in 7.3.2 (3)

ξ_1 according to Expression (7.5)

k_t is a factor dependent on the duration of the load

$k_t = 0,6$ for short term loading
$k_t = 0,4$ for long term loading

(3) In situations where bonded reinforcement is fixed at reasonably close centres within the tension zone (spacing $\leq 5(c+\phi/2)$, the maximum final crack spacing may be calculated from Expression (7.11) (see Figure 7.2):

$\boxed{A}$ - Neutral axis

$\boxed{B}$ - Concrete tension surface

$\boxed{C}$ - Crack spacing predicted by Expression (7.14)

$\boxed{D}$ - Crack spacing predicted by Expression (7.11)

$\boxed{E}$ - Actual crack width
Figure 7.2: Crack width, w, at concrete surface relative to distance from bar

$$s_{r,max} = k_3 c + k_1 k_2 k_4 \phi / \rho_{p,eff} \tag{7.11}$$

where:

ϕ is the bar diameter. Where a mixture of bar diameters is used in a section, an equivalent diameter, ϕ_{eq}, should be used. For a section with n_1 bars of diameter ϕ_1 and n_2 bars of diameter ϕ_2, the following expression should be used

$$\phi_{eq} = \frac{n_1\phi_1^2 + n_2\phi_2^2}{n_1\phi_1 + n_2\phi_2} \tag{7.12}$$

c is the cover to the longitudinal reinforcement
k_1 is a coefficient which takes account of the bond properties of the bonded reinforcement:
     = 0,8 for high bond bars
     = 1,6 for bars with an effectively plain surface (e.g. prestressing tendons)
k_2 is a coefficient which takes account of the distribution of strain:
     = 0,5 for bending
     = 1,0 for pure tension
     For cases of eccentric tension or for local areas, intermediate values of k_2 should be used which may be calculated from the relation:

$$k_2 = (\varepsilon_1 + \varepsilon_2)/2\varepsilon_1 \tag{7.13}$$

Where ε_1 is the greater and ε_2 is the lesser tensile strain at the boundaries of the section considered, assessed on the basis of a cracked section

Note: The values of k_3 and k_4 for use in a Country may be found in its National Annex. The recommended values are 3,4 and 0,425 respectively.

Where the spacing of the bonded reinforcement exceeds $5(c+\phi/2)$ (see Figure 7.2) or where there is no bonded reinforcement within the tension zone, an upper bound to the crack width may be found by assuming a maximum crack spacing:

$$s_{r,max} = 1,3\ (h - x) \tag{7.14}$$

(4) Where the angle between the axes of principal stress and the direction of the reinforcement, for members reinforced in two orthogonal directions, is significant (>15°), then the crack spacing $s_{r,max}$ may be calculated from the following expression:

$$s_{r,max} = \frac{1}{\dfrac{\cos\theta}{s_{r,max,y}} + \dfrac{\sin\theta}{s_{r,max,z}}} \tag{7.15}$$

where:

θ is the angle between the reinforcement in the y direction and the direction of the principal tensile stress

$s_{r,max,y}$ $s_{r,max,z}$ are the crack spacings calculated in the y and z directions respectively, according to 7.3.4 (3)

(5) For walls subjected to early thermal contraction where the horizontal steel area, A_s does not fulfil the requirements of 7.3.2 and where the bottom of the wall is restrained by a previously cast base, $s_{r,max}$ may be assumed to be equal to 1,3 times the height of the wall.

Note: Where simplified methods of calculating crack width are used they should be based on the properties given in this Standard or substantiated by tests.

7.4   Deflection control

7.4.1 General considerations

(1)P The deformation of a member or structure shall not be such that it adversely affects its proper functioning or appearance.

(2) Appropriate limiting values of deflection taking into account the nature of the structure, of the finishes, partitions and fixings and upon the function of the structure should be established.

(3) Deformations should not exceed those that can be accommodated by other connected elements such as partitions, glazing, cladding, services or finishes. In some cases limitation may be required to ensure the proper functioning of machinery or apparatus supported by the structure, or to avoid ponding on flat roofs.

Note: The limiting deflections given in (4) and (5) below are derived from ISO 4356 and should generally result in satisfactory performance of buildings such as dwellings, offices, public buildings or factories. Care should be taken to ensure that the limits are appropriate for the particular structure considered and that that there are no special requirements. Further information on deflections and limiting values may be obtained from ISO 4356.

(4) The appearance and general utility of the structure could be impaired when the calculated sag of a beam, slab or cantilever subjected to quasi-permanent loads exceeds span/250. The sag is assessed relative to the supports. Pre-camber may be used to compensate for some or

all of the deflection but any upward deflection incorporated in the formwork should not generally exceed span/250.

(5) Deflections that could damage adjacent parts of the structure should be limited. For the deflection after construction, span/500 is normally an appropriate limit for quasi-permanent loads. Other limits may be considered, depending on the sensitivity of adjacent parts.

(6) The limit state of deformation may be checked by either:
- by limiting the span/depth ratio, according to 7.4.2 or
- by comparing a calculated deflection, according to 7.4.3, with a limit value

Note: The actual deformations may differ from the estimated values, particularly if the values of applied moments are close to the cracking moment. The differences will depend on the dispersion of the material properties, on the environmental conditions, on the load history, on the restraints at the supports, ground conditions, etc.

7.4.2 Cases where calculations may be omitted

(1)P Generally, it is not necessary to calculate the deflections explicitly as simple rules, for example limits to span/depth ratio may be formulated, which will be adequate for avoiding deflection problems in normal circumstances. More rigorous checks are necessary for members which lie outside such limits, or where deflection limits other than those implicit in simplified methods are appropriate.

(2) Provided that reinforced concrete beams or slabs in buildings are dimensioned so that they comply with the limits of span to depth ratio given in this clause, their deflections may be considered as not exceeding the limits set out in 7.4.1 (4) and (5). The limiting span/depth ratio may be estimated using Expressions (7.16.a) and (7.16.b) and multiplying this by correction factors to allow for the type of reinforcement used and other variables. No allowance has been made for any pre-camber in the derivation of these Expressions.

$$\frac{l}{d} = K\left[11 + 1{,}5\sqrt{f_{ck}}\,\frac{\rho_0}{\rho} + 3{,}2\sqrt{f_{ck}}\left(\frac{\rho_0}{\rho} - 1\right)^{3/2}\right] \quad \text{if } \rho \le \rho_0 \tag{7.16.a}$$

$$\frac{l}{d} = K\left[11 + 1{,}5\sqrt{f_{ck}}\,\frac{\rho_0}{\rho - \rho'} + \frac{1}{12}\sqrt{f_{ck}}\sqrt{\frac{\rho'}{\rho_0}}\right] \quad \text{if } \rho > \rho_0 \tag{7.16.b}$$

where:
l/d is the limit span/depth
K is the factor to take into account the different structural systems
ρ_0 is the reference reinforcement ratio = $\sqrt{f_{ck}}\,10^{-3}$
ρ is the required tension reinforcement ratio at mid-span to resist the moment due to the design loads (at support for cantilevers)
ρ' is the required compression reinforcement ratio at mid-span to resist the moment due to design loads (at support for cantilevers)
f_{ck} is in MPa units

Expressions (7.16.a) and (7.16.b) have been derived on the assumption that the steel stress, under the appropriate design load at SLS at a cracked section at the mid-span of a beam or slab or at the support of a cantilever, is 310 MPa, (corresponding roughly to f_{yk} = 500 MPa).

Where other stress levels are used, the values obtained using Expression (7.16) should be multiplied by $310/\sigma_s$. It will normally be conservative to assume that:

$$310 / \sigma_s = 500 /(f_{yk} A_{s,req} / A_{s,prov}) \tag{7.17}$$

where:

σ_s is the tensile steel stress at mid-span (at support for cantilevers) under the design load at SLS

$A_{s,prov}$ is the area of steel provided at this section

$A_{s,req}$ is the area of steel required at this section for ultimate limit state

For flanged sections where the ratio of the flange breadth to the rib breadth exceeds 3, the values of l/d given by Expression (7.16) should be multiplied by 0,8.

For beams and slabs, other than flat slabs, with spans exceeding 7 m, which support partitions liable to be damaged by excessive deflections, the values of l/d given by Expression (7.16) should be multiplied by 7 / l_{eff} (l_{eff} in metres, see 5.3.2.2 (1)).

For flat slabs where the greater span exceeds 8,5 m, and which support partitions liable to be damaged by excessive deflections, the values of l/d given by Expression (7.16) should be multiplied by 8,5 / l_{eff} (l_{eff} in metres).

Note: Values of K for use in a Country may be found in its National Annex. Recommended values of K are given in Table 7.4N. Values obtained using Expression (7.16) for common cases (C30, σ_s = 310 MPa, different structural systems and reinforcement ratios ρ = 0,5 % and ρ = 1,5 %) are also given.

Table 7.4N: **Basic ratios of span/effective depth for reinforced concrete members without axial compression**

Structural System	K	Concrete highly stressed $\rho = 1,5\%$	Concrete lightly stressed $\rho = 0,5\%$
Simply supported beam, one- or two-way spanning simply supported slab	1,0	14	20
End span of continuous beam or one-way continuous slab or two-way spanning slab continuous over one long side	1,3	18	26
Interior span of beam or one-way or two-way spanning slab	1,5	20	30
Slab supported on columns without beams (flat slab) (based on longer span)	1,2	17	24
Cantilever	0,4	6	8

Note 1: The values given have been chosen to be generally conservative and calculation may frequently show that thinner members are possible.

Note 2: For 2-way spanning slabs, the check should be carried out on the basis of the shorter span. For flat slabs the longer span should be taken.

Note 3: The limits given for flat slabs correspond to a less severe limitation than a mid-span deflection of span/250 relative to the columns. Experience has shown this to be satisfactory.

The values given by Expression (7.16) and Table 7.4N have been derived from results of a parametric study made for a series of beams or slabs simply supported with rectangular cross section, using the general

approach given in 7.4.3. Different values of concrete strength class and a 500 MPa characteristic yield strength were considered. For a given area of tension reinforcement the ultimate moment was calculated and the quasi-permanent load was assumed as 50% of the corresponding total design load. The span/depth limits obtained satisfy the limiting deflection given in 7.4.1(5).

7.4.3 Checking deflections by calculation

(1)P Where a calculation is deemed necessary, the deformations shall be calculated under load conditions which are appropriate to the purpose of the check.

(2)P The calculation method adopted shall represent the true behaviour of the structure under relevant actions to an accuracy appropriate to the objectives of the calculation.

(3) Members which are not expected to be loaded above the level which would cause the tensile strength of the concrete to be exceeded anywhere within the member should be considered to be uncracked. Members which are expected to crack, but may not be fully cracked, will behave in a manner intermediate between the uncracked and fully cracked conditions and, for members subjected mainly to flexure, an adequate prediction of behaviour is given by Expression (7.18):

$$\alpha = \zeta\alpha_{II} + (1 - \zeta)\alpha_I \tag{7.18}$$

where

α is the deformation parameter considered which may be, for example, a strain, a curvature, or a rotation. (As a simplification, α may also be taken as a deflection - see (6) below)

α_I, α_{II} are the values of the parameter calculated for the uncracked and fully cracked conditions respectively

ζ is a distribution coefficient (allowing for tensioning stiffening at a section) given by Expression (7.19):

$$\zeta = 1 - \beta\left(\frac{\sigma_{sr}}{\sigma_s}\right)^2 \tag{7.19}$$

$\zeta = 0$ for uncracked sections

β is a coefficient taking account of the influence of the duration of the loading or of repeated loading on the average strain

= 1,0 for a single short-term loading

= 0,5 for sustained loads or many cycles of repeated loading

σ_s is the stress in the tension reinforcement calculated on the basis of a cracked section

σ_{sr} is the stress in the tension reinforcement calculated on the basis of a cracked section under the loading conditions causing first cracking

Note: σ_{sr}/σ_s may be replaced by M_{cr}/M for flexure or N_{cr}/N for pure tension, where M_{cr} is the cracking moment and N_{cr} is the cracking force.

(4) Deformations due to loading may be assessed using the tensile strength and the effective modulus of elasticity of the concrete (see (5)).

Table 3.1 indicates the range of likely values for tensile strength. In general, the best estimate of the behaviour will be obtained if f_{ctm} is used. Where it can be shown that there are no axial tensile stresses (e.g. those caused by shrinkage or thermal effects) the flexural tensile strength, $f_{ctm,fl}$, (see 3.1.8) may be used.

(5) For loads with a duration causing creep, the total deformation including creep may be calculated by using an effective modulus of elasticity for concrete according to Expression (7.20):

$$E_{c,eff} = \frac{E_{cm}}{1 + \varphi(\infty, t_0)}$$
(7.20)

where:

$\varphi(\infty, t_0)$ is the creep coefficient relevant for the load and time interval (see 3.1.3)

(6) Shrinkage curvatures may be assessed using Expression (7.21):

$$\frac{1}{r_{cs}} = \varepsilon_{cs} \alpha_e \frac{S}{I}$$
(7.21)

where:

$1/r_{cs}$ is the curvature due to shrinkage
ε_{cs} is the free shrinkage strain (see 3.1.4)
S is the first moment of area of the reinforcement about the centroid of the section
I is the second moment of area of the section
α_e is the effective modular ratio
$\quad \alpha_e = E_s / E_{c,eff}$

S and I should be calculated for the uncracked condition and the fully cracked condition, the final curvature being assessed by use of Expression (7.18).

(7) The most rigorous method of assessing deflections using the method given in (3) above is to compute the curvatures at frequent sections along the member and then calculate the deflection by numerical integration. In most cases it will be acceptable to compute the deflection twice, assuming the whole member to be in the uncracked and fully cracked condition in turn, and then interpolate using Expression (7.18).

Note: Where simplified methods of calculating deflections are used they should be based on the properties given in this Standard and substantiated by tests.

SECTION 8 DETAILING OF REINFORCEMENT AND PRESTRESSING TENDONS - GENERAL

8.1 General

(1)P The rules given in this Section apply to ribbed reinforcement, mesh and prestressing tendons subjected predominantly to static loading. They are applicable for normal buildings and bridges. They may not be sufficient for:
  - elements subjected to dynamic loading caused by seismic effects or machine vibration, impact loading and
  - to elements incorporating specially painted, epoxy or zinc coated bars.

Additional rules are provided for large diameter bars.

(2)P The requirements concerning minimum concrete cover shall be satisfied (see 4.4.1.2).

(3) For lightweight aggregate concrete, supplementary rules are given in Section 11.

(4) Rules for structures subjected to fatigue loading are given in 6.8.

8.2 Spacing of bars

(1)P The spacing of bars shall be such that the concrete can be placed and compacted satisfactorily for the development of adequate bond.

(2) The clear distance (horizontal and vertical) between individual parallel bars or horizontal layers of parallel bars should be not less than the maximum of $k_1 \cdot$bar diameter, $(d_g + k_2$ mm) or 20 mm where d_g is the maximum size of aggregate.

> **Note:** The value of k_1 and k_2 for use in a Country may be found in its National Annex. The recommended values are 1 and 5 mm respectively.

(3) Where bars are positioned in separate horizontal layers, the bars in each layer should be located vertically above each other. There should be sufficient space between the resulting columns of bars to allow access for vibrators and good compaction of the concrete.

(4) Lapped bars may be allowed to touch one another within the lap length. See 8.7 for more details.

8.3 Permissible mandrel diameters for bent bars

(1)P The minimum diameter to which a bar is bent shall be such as to avoid bending cracks in the bar, and to avoid failure of the concrete inside the bend of the bar.

(2) In order to avoid damage to the reinforcement the diameter to which the bar is bent (Mandrel diameter) should not be less than $\phi_{m,min}$.
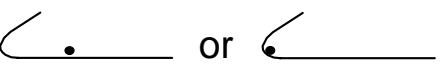

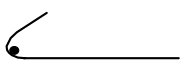

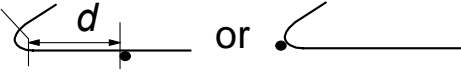

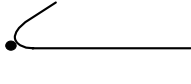

> **Note:** The values of $\phi_{m,min}$ for use in a Country may be found in its National Annex. The recommended values are given in Table 8.1N.

Table 8.1N: Minimum mandrel diameter to avoid damage to reinforcement

a) for bars and wire

Bar diameter	Minimum mandrel diameter for bends, hooks and loops (see Figure 8.1)
$\phi \leq 16$ mm	4ϕ
$\phi > 16$ mm	7ϕ

b) for welded bent reinforcement and mesh bent after welding

Minimum mandrel diameter	
5ϕ	$d \geq 3\phi$: $\qquad$ 5ϕ $d < 3\phi$ or welding within the curved zone: 20ϕ
Note: The mandrel size for welding within the curved zone may be reduced to 5ϕ where the welding is carried out in accordance with prEN ISO 17660 Annex B	

(3) The mandrel diameter need not be checked to avoid concrete failure if the following conditions exist:
- the anchorage of the bar does not require a length more than 5ϕ past the end of the bend;
- the bar is not positioned at the edge (plane of bend close to concrete face) and there is a cross bar with a diameter $\geq \phi$ inside the bend.
- the mandrel diameter is at least equal to the recommended values given in Table 8.1N.

Otherwise the mandrel diameter, $\phi_{m,min}$, should be increased in accordance with Expression (8.1)

$$\phi_{m,min} \geq F_{bt} \left((1/a_b) + 1/(2\phi) \right) / f_{cd} \tag{8.1}$$

where:
- F_{bt} is the tensile force from ultimate loads in a bar or group of bars in contact at the start of a bend
- a_b for a given bar (or group of bars in contact) is half of the centre-to-centre distance between bars (or groups of bars) perpendicular to the plane of the bend. For a bar or group of bars adjacent to the face of the member, a_b should be taken as the cover plus $\phi/2$

The value of f_{cd} should not be taken greater than that for concrete class C55/67.

8.4   Anchorage of longitudinal reinforcement

8.4.1 General

(1)P Reinforcing bars, wires or welded mesh fabrics shall be so anchored that the bond forces are safely transmitted to the concrete avoiding longitudinal cracking or spalling. Transverse reinforcement shall be provided if necessary.

(2) Methods of anchorage are shown in Figure 8.1 (see also 8.8 (3)).

a) **Basic tension anchorage length, l_b, for any shape measured along the centreline**

b) **Equivalent anchorage length for standard bend**

c) **Equivalent anchorage length for standard hook**

d) **Equivalent anchorage length for standard loop**

e) **Equivalent anchorage length for welded transverse bar**
Figure 8.1: Methods of anchorage other than by a straight bar

(3) Bends and hooks do not contribute to compression anchorages.

(4) Concrete failure inside bends should be prevented by complying with 8.3 (3).

(5) Where mechanical devices are used the test requirements should be in accordance with the relevant product standard or a European Technical Approval.

(6) For the transmission of prestressing forces to the concrete, see 8.10.

8.4.2 Ultimate bond stress

(1)P The ultimate bond strength shall be sufficient to prevent bond failure.

(2) The design value of the ultimate bond stress, f_{bd}, for ribbed bars may be taken as:

$$f_{bd} = 2{,}25 \, \eta_1 \, \eta_2 \, f_{ctd} \qquad\qquad (8.2)$$

where:
  f_{ctd} is the design value of concrete tensile strength according to 3.1.6 (2)P. Due to the increasing brittleness of higher strength concrete, $f_{ctk,0,05}$ should be limited here to the value for C60/75, unless it can be verified that the average bond strength increases above this limit
  η_1 is a coefficient related to the quality of the bond condition and the position of the bar during concreting (see Figure 8.2):
   $\eta_1 = 1{,}0$ when 'good' conditions are obtained and

133

η_1 = 0,7 for all other cases and for bars in structural elements built with slip-forms, unless it can be shown that 'good' bond conditions exist

η_2 is related to the bar diameter:

η_2 = 1,0 for $\phi \leq 32$ mm

η_2 = (132 - ϕ)/100 for $\phi > 32$ mm

A

A

250

a) & b) 'good' bond conditions   **c) & d) unhatched zone – 'good' bond conditions**
for all bars   **hatched zone – 'poor' bond conditions**
Figure 8.2: Description of bond conditions

8.4.3 Basic anchorage length

(1)P The calculation of the required anchorage length shall take into consideration the type of steel and bond properties of the bars.

(2) The basic required anchorage length, $l_{b,rqd}$, for anchoring the force $A_s. \sigma_{sd}$ in a straight bar assuming constant bond stress equal to f_{bd} follows from:

$$l_{b,rqd} = (\phi / 4)\ (\sigma_{sd} / f_{bd}) \tag{8.3}$$

Where σ_{sd} is the design stress of the bar at the position from where the anchorage is measured from.

Values for f_{bd} are given in 8.4.2.

(3) For bent bars the basic anchorage length, l_b, and the design length, l_{bd}, should be measured along the centre-line of the bar (see Figure 8.1a).

(4) Where pairs of wires/bars form welded fabrics the diameter, ϕ, in Expression (8.3) should be replaced by the equivalent diameter $\phi_n = \phi\sqrt{2}$.

8.4.4 Design anchorage length

(1) The design anchorage length, l_{bd}, is:

$$l_{bd} = \alpha_1 \, \alpha_2 \, \alpha_3 \, \alpha_4 \, \alpha_5 \; l_{b,rqd} \geq l_{b,min} \tag{8.4}$$

where α_1, α_2, α_3, α_4 and α_5 are coefficients given in Table 8.2:

    α_1 is for the effect of the form of the bars assuming adequate cover (see Figure 8.1).

    α_2 is for the effect of concrete minimum cover (see Figure 8.3)
a) Straight bars   **b) Bent or hooked bars**   **c) Looped bars**
  $c_d = \min (a/2, c_1, c)$ $c_d = \min (a/2, c_1)$ $c_d = c$

Figure 8.3: Values of c_d for beams and slabs

    α_3 is for the effect of confinement by transverse reinforcement
    α_4 is for the influence of one or more welded transverse bars ($\phi_t > 0,6\phi$) along the design anchorage length l_{bd} (see also 8.6)
    α_5 is for the effect of the pressure transverse to the plane of splitting along the design anchorage length

The product $(\alpha_2\alpha_3\alpha_5) \geq 0,7$ (8.5)

$l_{b,rqd}$ is taken from Expression (8.3)
$l_{b,min}$ is the minimum anchorage length if no other limitation is applied:
    - for anchorages in tension: $l_{b,min} > \max\{0,3l_{b,rqd}; 10\phi; 100 \text{ mm}\}$ (8.6)
    - for anchorages in compression: $l_{b,min} > \max\{0,6l_{b,rqd}; 10\phi; 100 \text{ mm}\}$ (8.7)

(2) As a simplified alternative to 8.4.4 (1) the tension anchorage of certain shapes shown in Figure 8.1 may be provided as an equivalent anchorage length, $l_{b,eq}$. $l_{b,eq}$ is defined in this figure and may be taken as:
  - $\alpha_1 l_{b,rqd}$ for shapes shown in Figure 8.1b to 8.1d (see Table 8.2 for values of α_1)
  - $\alpha_4 l_{b,rqd}$ for shapes shown in Figure 8.1e (see Table 8.2 for values of α_4).

  where
    α_1 and α_4 are defined in (1)
    $l_{b,rqd}$ is calculated from Expression (8.3)

Table 8.2: Values of α_1, α_2, α_3, α_4 and α_5 coefficients

Influencing factor	Type of anchorage	Reinforcement bar	
		In tension	In compression
Shape of bars	Straight	$\alpha_1 = 1,0$	$\alpha_1 = 1,0$
	Other than straight (see Figure 8.1 (b), (c) and (d)	$\alpha_1 = 0,7$ if $c_d > 3\phi$ otherwise $\alpha_1 = 1,0$ (see Figure 8.3 for values of c_d)	$\alpha_1 = 1,0$
Concrete cover	Straight	$\alpha_2 = 1 - 0,15\,(c_d - \phi)/\phi$ $\geq 0,7$ $\leq 1,0$	$\alpha_2 = 1,0$
	Other than straight (see Figure 8.1 (b), (c) and (d))	$\alpha_2 = 1 - 0,15\,(c_d - 3\phi)/\phi$ $\geq 0,7$ $\leq 1,0$ (see Figure 8.3 for values of c_d)	$\alpha_2 = 1,0$
Confinement by transverse reinforcement not welded to main reinforcement	All types	$\alpha_3 = 1 - K\lambda$ $\geq 0,7$ $\leq 1,0$	$\alpha_3 = 1,0$
Confinement by welded transverse reinforcement*	All types, position and size as specified in Figure 8.1 (e)	$\alpha_4 = 0,7$	$\alpha_4 = 0,7$
Confinement by transverse pressure	All types	$\alpha_5 = 1 - 0,04p$ $\geq 0,7$ $\leq 1,0$	-
where: $\lambda = (\Sigma A_{st} - \Sigma A_{st,min})/A_s$ ΣA_{st} cross-sectional area of the transverse reinforcement along the design anchorage length l_{bd} $\Sigma A_{st,min}$ cross-sectional area of the minimum transverse reinforcement $= 0,25\,A_s$ for beams and 0 for slabs A_s area of a single anchored bar with maximum bar diameter K values shown in Figure 8.4 p transverse pressure [MPa] at ultimate limit state along l_{bd}			
* See also 8.6: For direct supports l_{bd} may be taken less than $l_{b,min}$ provided that there is at least one transverse wire welded within the support. This should be at least 15 mm from the face of the support.			

$K = 0,1$ $K = 0,05$ $K = 0$
Figure 8.4: Values of K for beams and slabs

8.5   Anchorage of links and shear reinforcement

(1) The anchorage of links and shear reinforcement should normally be effected by means of bends and hooks, or by welded transverse reinforcement. A bar should be provided inside a hook or bend.

(2) The anchorage should comply with Figure 8.5. Welding should be carried out in accordance with EN ISO 17660 and have a welding capacity in accordance with 8.6 (2).

> **Note:** For definition of the bend angles see Figure 8.1.
> **Note:** For c) and d) the cover should not be less than either 3ϕ or 50 mm.

Figure 8.5: Anchorage of links

8.6   Anchorage by welded bars

(1)   Additional anchorage to that of 8.4 and 8.5 may be obtained by transverse welded bars (see Figure 8.6) bearing on the concrete. The quality of the welded joints should be shown to be adequate.
Figure 8.6: Welded transverse bar as anchoring device

(2) The anchorage capacity of one welded transverse bar (diameter 14 mm- 32 mm), welded on the inside of the main bar, is F_{btd}. σ_{sd} in Expression (8.3) may then be reduced by F_{btd}/A_s, where A_s is the area of the bar.

> **Note:** The value of F_{btd} for use in a Country may be found in its National Annex. The recommended value is determined from:
>
> $F_{btd} = l_{td} \, \phi_t \, \sigma_{td}$ but not greater than F_{wd} (8.8N)
>
> where:
> F_{wd} is the design shear strength of weld (specified as a factor times $A_s \, f_{yd}$; say 0.5 $A_s \, f_{yd}$ where A_s is the cross-section of the anchored bar and f_{yd} is its design yield strength)

l_{td} is the design length of transverse bar: $l_{td} = 1,16 \, \phi_t \, (f_{yd}/\sigma_{td})^{0,5} \leq l_t$

l_t is the length of transverse bar, but not more than the spacing of bars to be anchored

ϕ_t is the diameter of transverse bar

σ_{td} is the concrete stress; $\sigma_{td} = (f_{ctd} + \sigma_{cm})/y \leq 3 \, f_{cd}$

σ_{cm} is the compression in the concrete perpendicular to both bars (mean value, positive for compression)

y is a function: $y = 0,015 + 0,14 \, e^{(-0,18x)}$

x is a function accounting for the geometry: $x = 2 \, (c/\phi_t) + 1$

c is the concrete cover perpendicular to both bars

(3) If two bars of the same size are welded on opposite sides of the bar to be anchored, the capacity calculated from 8.6 (2) may be doubled provided that the cover to the outer bar is in accordance with Section 4.

(4) If two bars are welded to the same side with a minimum spacing of 3ϕ, the capacity should be multiplied by a factor of 1,41.

(5) For nominal bar diameters of 12 mm and less, the anchorage capacity of a welded cross bar is mainly dependent on the design strength of the welded joint. It may be calculated as follows:

$$F_{btd} = F_{wd} \leq 16 \, A_s \, f_{cd} \, \phi_t \, / \, \phi_l \qquad\qquad (8.9)$$

where:

F_{wd} design shear strength of weld (see 8.6 (2))

ϕ_t nominal diameter of transverse bar: $\phi_t \leq 12$ mm

ϕ_l nominal diameter of bar to anchor: $\phi_l \leq 12$ mm

If two welded cross bars with a minimum spacing of ϕ_t are used, the anchorage length given by Expression (8.9) should be multiplied by a factor of 1,41.

8.7 Laps and mechanical couplers

8.7.1 General

(1)P Forces are transmitted from one bar to another by:
- lapping of bars, with or without bends or hooks;
- welding;
- mechanical devices assuring load transfer in tension-compression or in compression only.

8.7.2 Laps

(1)P The detailing of laps between bars shall be such that:
- the transmission of the forces from one bar to the next is assured;
- spalling of the concrete in the neighbourhood of the joints does not occur;
- large cracks which affect the performance of the structure do not occur.

(2) Laps:
- between bars should normally be staggered and not located in areas of high moments /forces (e.g. plastic hinges). Exceptions are given in (4) below;
- at any section should normally be arranged symmetrically.

(3) The arrangement of lapped bars should comply with Figure 8.7:
- the clear distance between lapped bars should not be greater than 4ϕ or 50 mm,

otherwise the lap length should be increased by a length equal to the clear space where it exceeds 4ϕ or 50 mm;

- the longitudinal distance between two adjacent laps should not be less than 0,3 times the lap length, l_0;
- In case of adjacent laps, the clear distance between adjacent bars should not be less than 2ϕ or 20 mm.

(4) When the provisions comply with (3) above, the permissible percentage of lapped bars in tension may be 100% where the bars are all in one layer. Where the bars are in several layers the percentage should be reduced to 50%.

All bars in compression and secondary (distribution) reinforcement may be lapped in one section.
Figure 8.7: Adjacent laps

8.7.3 Lap length

(1) The design lap length is:

$$l_0 = \alpha_1\, \alpha_2\, \alpha_3\, \alpha_5\, \alpha_6\, l_{b,rqd}\ \geq l_{0,min} \qquad\qquad (8.10)$$

where:
$l_{b,rqd}$ is calculated from Expression (8.3)

$$l_{0,min} > \max\{0,3\, \alpha_6\, l_{b,rqd};\ 15\phi;\ 200\ \text{mm}\} \qquad\qquad (8.11)$$

Values of α_1, α_2, α_3 and α_5 may be taken from Table 8.2; however, for the calculation of α_3, $\Sigma A_{st,min}$ should be taken as $1,0A_s(\sigma_{sd}/f_{yd})$, with A_s = area of one lapped bar.

$\alpha_6 = (\rho_1/25)^{0,5}$ but not exceeding 1,5 nor less than 1,0, where ρ_1 is the percentage of reinforcement lapped within $0,65\ l_0$ from the centre of the lap length considered (see Figure 8.8). Values of α_6 are given in Table 8.3.

Table 8.3: Values of the coefficient α_6

Percentage of lapped bars relative to the total cross-section area	< 25%	33%	50%	>50%
α_6	1	1,15	1,4	1,5
Note: Intermediate values may be determined by interpolation.				

| A | Section considered | B | Bar I | C | Bar II | D | Bar III | E | Bar IV |
Example: Bars II and III are outside the section being considered: % = 50 and α_6 =1,4

Figure 8.8: Percentage of lapped bars in one lapped section

8.7.4 Transverse reinforcement in the lap zone

8.7.4.1 Transverse reinforcement for bars in tension

(1) Transverse reinforcement is required in the lap zone to resist transverse tension forces.

(2) Where the diameter, ϕ, of the lapped bars is less than 20 mm, or the percentage of lapped bars in any section is less than 25%, then any transverse reinforcement or links necessary for other reasons may be assumed sufficient for the transverse tensile forces without further justification.

(3) Where the diameter, ϕ, of the lapped bars is greater than or equal to 20 mm, the transverse reinforcement should have a total area, A_{st} (sum of all legs parallel to the layer of the spliced reinforcement) of not less than the area A_s of one lapped bar ($\Sigma A_{st} \geq 1,0 A_s$). The transverse bar should be placed perpendicular to the direction of the lapped reinforcement and between that and the surface of the concrete.

If more than 50% of the reinforcement is lapped at one point and the distance, a, between adjacent laps at a section is $\leq 10\phi$ (see Figure 8.7) transverse reinforcement should be formed by links or U bars anchored into the body of the section.

(4) The transverse reinforcement provided for (3) above should be positioned at the outer sections of the lap as shown in Figure 8.9(a).

8.7.4.2 Transverse reinforcement for bars permanently in compression

(1) In addition to the rules for bars in tension one bar of the transverse reinforcement should be placed outside each end of the lap length and within 4ϕ of the ends of the lap length (Figure 8.9b).

a) bars in tension

b) bars in compression
Figure 8.9: Transverse reinforcement for lapped splices

8.7.5 Laps for welded mesh fabrics made of ribbed wires

8.7.5.1 Laps of the main reinforcement

(1) Laps may be made either by intermeshing or by layering of the fabrics (Figure 8.10).

a) intermeshed fabric (longitudinal section)

b) layered fabric (longitudinal section)
Figure 8.10: Lapping of welded fabric

(2) Where fatigue loads occur, intermeshing should be adopted

(3) For intermeshed fabric, the lapping arrangements for the main longitudinal bars should conform with 8.7.2. Any favourable effects of the transverse bars should be ignored: thus taking $\alpha_3 = 1,0$.

(4)   For layered fabric, the laps of the main reinforcement should generally be situated in zones where the calculated stress in the reinforcement at ultimate limit state is not more than 80% of the design strength.

(5) Where condition (4) above is not fulfilled, the effective depth of the steel for the calculation of bending resistance in accordance with 6.1 should apply to the layer furthest from the tension face. In addition, when carrying out a crack-verification next to the end of the lap, the steel stress used in Tables 7.2 and 7.3 should be increased by 25% due to the discontinuity at the ends of the laps,.

(6) The percentage of the main reinforcement, which may be lapped in any one section, should comply with the following:

For intermeshed fabric, the values given in Table 8.3 are applicable.

For layered fabric the permissible percentage of the main reinforcement that may be spliced by lapping in any section, depends on the specific cross-section area of the welded fabric provided $(A_s/s)_{prov}$, where s is the spacing of the wires:

- 100%   if $(A_s/s)_{prov} \leq 1200$ mm^2/m

- 60%   if $(A_s/s)_{prov} > 1200$ mm^2/m.

The joints of the multiple layers should be staggered by at least $1{,}3l_0$ (l_0 is determined from 8.7.3).

(7) Additional transverse reinforcement is not necessary in the lapping zone.

8.7.5.2 Laps of secondary or distribution reinforcement

(1) All secondary reinforcement may be lapped at the same location.

The minimum values of the lap length l_0 are given in Table 8.4; the lap length of two secondary bars should cover two main bars.

Table 8.4: Required lap lengths for secondary wires of fabrics

Diameter of secondary wires (mm)	Lap lengths
$\phi \leq 6$	≥ 150 mm; at least 1 wire pitch within the lap length
$6 < \phi \leq 8{,}5$	≥ 250 mm; at least 2 wire pitches
$8{,}5 < \phi \leq 12$	≥ 350 mm; at least 2 wire pitches

8.8   Additional rules for large diameter bars

(1) For bars with a diameter larger than ϕ_{large} the following rules supplement those given in 8.4 and 8.7.

   Note: The value of ϕ_{large} for use in a Country may be found in its National Annex. The recommended value is 32 mm.

142

(2) When such large diameter bars are used, crack control may be achieved either by using surface reinforcement (see 9.2.4) or by calculation (see 7.3.4).

(3) Splitting forces are higher and dowel action is greater with the use of large diameter bars. Such bars should be anchored with mechanical devices. As an alternative they may be anchored as straight bars, but links should be provided as confining reinforcement.

(4) Generally large diameter bars should not be lapped. Exceptions include sections with a minimum dimension 1,0 m or where the stress is not greater than 80% of the design ultimate strength.

(5) Transverse reinforcement, additional to that for shear, should be provided in the anchorage zones where transverse compression is not present.

(6) For straight anchorage lengths (see Figure 8.11 for the notation used) the additional reinforcement referred to in (5) above should not be less than the following:
   - in the direction parallel to the tension face:

$$A_{sh} = 0,25 \, A_s \, n_1 \qquad\qquad (8.12)$$

   - in the direction perpendicular to the tension face:

$$A_{sv} = 0,25 \, A_s \, n_2 \qquad\qquad (8.13)$$

where:
   A_s is the cross sectional area of an anchored bar,
   n_1 is the number of layers with bars anchored at the same point in the member
   n_2 is the number of bars anchored in each layer.

(7) The additional transverse reinforcement should be uniformly distributed in the anchorage zone and the spacing of bars should not exceed 5 times the diameter of the longitudinal reinforcement.
Example: In the left hand case $n_1 = 1$, $n_2 = 2$ and in the right hand case $n_1 = 2$, $n_2 = 2$

Figure 8.11: Additional reinforcement in an anchorage for large diameter bars where there is no transverse compression.

(8) For surface reinforcement, 9.2.4 applies, but the area of surface reinforcement should not be less than 0,01 $A_{ct,ext}$ in the direction perpendicular to large diameter bars, and 0,02 $A_{ct,ext}$ parallel to those bars.

8.9 Bundled bars

8.9.1 General

(1) Unless otherwise stated, the rules for individual bars also apply for bundles of bars. In a bundle, all the bars should be of the same characteristics (type and grade). Bars of different sizes may be bundled provided that the ratio of diameters does not exceed 1,7.

(2) In design, the bundle is replaced by a notional bar having the same sectional area and the same centre of gravity as the bundle. The equivalent diameter, ϕ_n of this notional bar is such that:

$$\phi_n = \phi \sqrt{n_b} \le 55 \text{ mm}\tag{8.14}$$

>   where
> n_b is the number of bars in the bundle, which is limited to:
> $n_b \le 4$ for vertical bars in compression and for bars in a lapped joint,
> $n_b \le 3$ for all other cases.

(3) For a bundle, the rules given in 8.2 for spacing of bars apply. The equivalent diameter, ϕ_n, should be used but the clear distance between bundles should be measured from the actual external contour of the bundle of bars. The concrete cover should be measured from the actual external contour of the bundles and should not be less than ϕ_n.

(4) Where two touching bars are positioned one above the other, and where the bond conditions are good, such bars need not be treated as a bundle.

8.9.2 Anchorage of bundles of bars

(1) Bundles of bars in tension may be curtailed over end and intermediate supports. Bundles with an equivalent diameter < 32 mm may be curtailed near a support without the need for staggering bars. Bundles with an equivalent diameter $\ge$ 32 mm which are anchored near a support should be staggered in the longitudinal direction as shown in Figure 8.12.

(2) Where individual bars are anchored with a staggered distance greater than 1,3 $l_{b,rqd}$ (where $l_{b,rqd}$ is based on the bar diameter), the diameter of the bar may be used in assessing l_{bd} (see Figure 8.12). Otherwise the equivalent diameter of the bundle, ϕ_n, should be used.
Figure 8.12: Anchorage of widely staggered bars in a bundle

(3) For compression anchorages bundled bars need not be staggered. For bundles with an equivalent diameter $\ge$ 32 mm, at least four links having a diameter $\ge$ 12 mm should be provided at the ends of the bundle. A further link should be provided just beyond the end of the curtailed bar.

8.9.3   Lapping bundles of bars

(1) The lap length should be calculated in accordance with 8.7.3 using ϕ_n (from 8.9.1 (2)) as the equivalent diameter of bar.

(2) For bundles which consist of two bars with an equivalent diameter < 32 mm the bars may be lapped without staggering individual bars. In this case the equivalent bar size should be used to calculate l_0.

(3) For bundles which consist of two bars with an equivalent diameter $\geq$ 32 mm or of three bars, individual bars should be staggered in the longitudinal direction by at least $1,3l_0$ as shown in Figure 8.13, where l_0 is based on a single bar. For this case bar No. 4 is used as the lapping bar. Care should be taken to ensure that there are not more than four bars in any lap cross section. Bundles of more than three bars should not be lapped.
Figure 8.13:   Lap joint in tension including a fourth bar

8.10   Prestressing tendons

8.10.1 Arrangement of prestressing tendons and ducts

8.10.1.1 General

(1)P The spacing of ducts or of pre-tensioned tendons shall be such as to ensure that placing and compacting of the concrete can be carried out satisfactorily and that sufficient bond can be attained between the concrete and the tendons.

8.10.1.2 Pre-tensioned tendons

(1) The minimum clear horizontal and vertical spacing of individual pre-tensioned tendons should be in accordance with that shown in Figure 8.14. Other layouts may be used provided that test results show satisfactory ultimate behaviour with respect to:
- the concrete in compression at the anchorage
- the spalling of concrete
- the anchorage of pre-tensioned tendons
- the placing of the concrete between the tendons.

Consideration should also be given to durability and the danger of corrosion of the tendon at the end of elements.
Note: Where ϕ is the diameter of pre-tensioned tendon and d_g is the maximum size of aggregate.

Figure 8.14: Minimum clear spacing between pre-tensioned tendons.

(2) Bundling of tendons should not occur in the anchorage zones, unless placing and compacting of the concrete can be carried out satisfactorily and sufficient bond can be attained between the concrete and the tendons.

8.10.1.3 Post-tension ducts

(1)P The ducts for post-tensioned tendons shall be located and constructed so that:
- the concrete can be safely placed without damaging the ducts;
- the concrete can resist the forces from the ducts in the curved parts during and after stressing;
- no grout will leak into other ducts during grouting process.

(2) Ducts for post-tensioned members, should not normally be bundled except in the case of a pair of ducts placed vertically one above the other.

(3) The minimum clear spacing between ducts should be in accordance with that shown in Figure 8.15.
Note: Where ϕ is the diameter of post-tension duct and d_g is the maximum size of aggregate.

Figure 8.15: Minimum clear spacing between ducts

8.10.2 Anchorage of pre-tensioned tendons

8.10.2.1 General

(1) In anchorage regions for pre-tensioned tendons, the following length parameters should be considered, see Figure 8.16:
  a) Transmission length, l_{pt}, over which the prestressing force (P_0) is fully transmitted to the

concrete; see 8.10.2.2 (2),

b) Dispersion length, l_{disp} over which the concrete stresses gradually disperse to a linear distribution across the concrete section; see 8.10.2.2 (4),

c) Anchorage length, l_{bpd}, over which the tendon force F_{pd} in the ultimate limit state is fully anchored in the concrete; see 8.10.2.3 (4) and (5).

A - **Linear stress distribution in member cross-section**
Figure 8.16: Transfer of prestress in pretensioned elements; length parameters

8.10.2.2 Transfer of prestress

(1) At release of tendons, the prestress may be assumed to be transferred to the concrete by a constant bond stress f_{bpt}, where:

$$f_{bpt} = \eta_{p1}\, \eta_1\, f_{ctd}(t) \tag{8.15}$$

where:

  η_{p1} is a coefficient that takes into account the type of tendon and the bond situation at release

  η_{p1} = 2,7 for indented wires

  η_{p1} = 3,2 for 3 and 7-wire strands

  η_1 = 1,0 for good bond conditions (see 8.4.2)

  = 0,7 otherwise, unless a higher value can be justified with regard to special circumstances in execution

  $f_{ctd}(t)$ is the design tensile value of strength at time of release; $f_{ctd}(t) = \alpha_{ct}{\cdot}0{,}7{\cdot}f_{ctm}(t) / \gamma_c$ (see also 3.1.2 (8) and 3.1.6 (2)P)

Note: Values of η_{p1} for types of tendons other than those given above may be used subject to a European Technical Approval

(2) The basic value of the transmission length, l_{pt}, is given by:

$$l_{pt} = \alpha_1 \alpha_2 \phi \sigma_{pm0}/f_{bpt} \tag{8.16}$$

where:

  α_1 = 1,0   for gradual release

  = 1,25   for sudden release

  α_2 = 0,25   for tendons with circular cross section

  = 0,19 for 3 and 7-wire strands

  ϕ is the nominal diameter of tendon

  σ_{pm0} is the tendon stress just after release

(3) The design value of the transmission length should be taken as the less favourable of two

147

values, depending on the design situation:

$$l_{pt1} = 0,8 \, l_{pt} \tag{8.17}$$

or

$$l_{pt2} = 1,2 \, l_{pt} \tag{8.18}$$

Note: Normally the lower value is used for verifications of local stresses at release, the higher value for ultimate limit states (shear, anchorage etc.).

(4) Concrete stresses may be assumed to have a linear distribution outside the dispersion length, see Figure 8.17:

$$l_{disp} = \sqrt{l_{pt}^2 + d^2} \tag{8.19}$$

(5) Alternative build-up of prestress may be assumed, if adequately justified and if the transmission length is modified accordingly.

8.10.2.3 Anchorage of tensile force for the ultimate limit state

(1) The anchorage of tendons should be checked in sections where the concrete tensile stress exceeds $f_{ctk,0,05}$. The tendon force should be calculated for a cracked section, including the effect of shear according to 6.2.3 (6); see also 9.2.1.3. Where the concrete tensile stress is less than $f_{ctk,0,05}$, no anchorage check is necessary.

(2) The bond strength for anchorage in the ultimate limit state is:

$$f_{bpd} = \eta_{p2} \, \eta_1 \, f_{ctd} \tag{8.20}$$

where:

η_{p2} is a coefficient that takes into account the type of tendon and the bond situation at anchorage

$\eta_{p2} = 1,4$ for indented wires or

$\eta_{p2} = 1,2$ for 7-wire strands

η_1 is as defined in 8.10.2.2 (1)

Note : Values of η_{p2} for types of tendons other than those given above may be used subject to a European Technical Approval.

(3) Due to increasing brittleness with higher concrete strength, $f_{ctk,0,05}$ should here be limited to the value for C60/75, unless it can be verified that the average bond strength increases above this limit.

(4) The total anchorage length for anchoring a tendon with stress σ_{pd} is:

$$l_{bpd} = l_{pt2} + \alpha_2 \phi(\sigma_{pd} - \sigma_{pm\infty})/f_{bpd} \tag{8.21}$$

where

l_{pt2} is the upper design value of transmission length, see 8.10.2.2 (3)

α_2 as defined in 8.10.2.2 (2)

σ_{pd} is the tendon stress corresponding to the force described in (1)

$\sigma_{pm\infty}$ is the prestress after all losses

(5) Tendon stresses in the anchorage zone are illustrated in Figure 8.17.

148
**Figure 8.17: Stresses in the anchorage zone of pre-tensioned members:
(1) at release of tendons, (2) at ultimate limit state**

(6) In case of combined ordinary and pre-tensioned reinforcement, the anchorage capacities of each may be summed.

8.10.3 Anchorage zones of post-tensioned members

(1) The design of anchorage zones should be in accordance with the application rules given in this clause and those in 6.5.3.

(2) When considering the effects of the prestress as a concentrated force on the anchorage zone, the design value of the prestressing tendons should be in accordance with 2.4.2.2 (3) and the lower characteristic tensile strength of the concrete should be used.

(3) The bearing stress behind anchorage plates should be checked in accordance with the relevant European Technical Approval.

(4) Tensile forces due to concentrated forces should be assessed by a strut and tie model, or other appropriate representation (see 6.5). Reinforcement should be detailed assuming that it acts at its design strength. If the stress in this reinforcement is limited to 300 MPa no check of crackwidths is necessary.

(5) As a simplification the prestressing force may be assumed to disperse at an angle of spread 2β (see Figure 8.18), starting at the end of the anchorage device, where β may be assumed to be arc tan 2/3.

Plan of flange

β = arc tan(2/3) = 33.7°
A - tendon

Figure 8.18: Dispersion of prestress

8.10.4 Anchorages and couplers for prestressing tendons

(1)P The anchorage devices used for post-tensioned tendons shall be in accordance with those specified for the prestressing system, and the anchorage lengths in the case of pre-tensioned tendons shall be such as to enable the full design strength of the tendons to be developed, taking account of any repeated, rapidly changing action effects.

(2)P Where couplers are used they shall be in accordance with those specified for the prestressing system and shall be so placed - taking account of the interference caused by these devices - that they do not affect the bearing capacity of the member and that any temporary anchorage which may be needed during construction can be introduced in a satisfactory manner.

(3) Calculations for local effects in the concrete and for the transverse reinforcement should be made in accordance with 6.5 and 8.10.3.

(4) In general, couplers should be located away from intermediate supports.

(5) The placing of couplers on 50% or more of the tendons at one cross-section should be avoided unless it can be shown that a higher percentage will not cause more risk to the safety of the structure.

8.10.5 Deviators

(1)P A deviator shall satisfy the following requirements:
- withstand both longitudinal and transverse forces that the tendon applies to it and transmit these forces to the structure;
- ensure that the radius of curvature of the prestressing tendon does not cause any overstressing or damage to it.

(2)P In the deviation zones the tubes forming the sheaths shall be able to sustain the radial pressure and longitudinal movement of the prestressing tendon, without damage and without impairing its proper functioning.

(3)P The radius of curvature of the tendon in a deviation zone shall be in accordance with EN 10138 and appropriate European Technical Approvals.

(4) Designed tendon deviations up to an angle of 0,01 radians may be permitted without using a deviator. The forces developed by the change of angle using a deviator in accordance with the relevant European Technical Approval should be taken into account in the design calculations.

SECTION 9   DETAILING OF MEMBERS AND PARTICULAR RULES

9.1   General

(1)P The requirements for safety, serviceability and durability are satisfied by following the rules given in this section in addition to the general rules given elsewhere.

(2) The detailing of members should be consistent with the design models adopted.

(3) Minimum areas of reinforcement are given in order to prevent a brittle failure, wide cracks and also to resist forces arising from restrained actions.

> **Note:** The rules given in this section are mainly applicable to reinforced concrete buildings.

9.2   Beams

9.2.1 Longitudinal reinforcement

9.2.1.1   Minimum and maximum reinforcement areas

(1) The area of longitudinal tension reinforcement should not be taken as less than $A_{s,min}$.

> **Note 1:** See also 7.3 for area of longitudinal tension reinforcement to control cracking.

> **Note 2:** The value of $A_{s,min}$ for beams for use in a Country may be found in its National Annex. The recommended value is given in the following:
>
> $$A_{s,min} = 0,26\frac{f_{ctm}}{f_{yk}}b_t d \qquad \text{but not less than } 0,0013 b_t d \qquad\qquad (9.1N)$$
>
> Where:
> > b_t denotes the mean width of the tension zone; for a T-beam with the flange in compression, only the width of the web is taken into account in calculating the value of b_t.
>
> > f_{ctm} should be determined with respect to the relevant strength class according to Table 3.1.
>
> Alternatively, for secondary elements, where some risk of brittle failure may be accepted, $A_{s,min}$ may be taken as 1,2 times the area required in ULS verification.

(2) Sections containing less reinforcement than $A_{s,min}$ should be considered as unreinforced (see Section 12).

(3) The cross-sectional area of tension or compression reinforcement should not exceed $A_{s,max}$ outside lap locations.

> **Note:** The value of $A_{s,max}$ for beams for use in a Country may be found in its National Annex. The recommended value is $0,04A_c$.

(4) For members prestressed with permanently unbonded tendons or with external prestressing cables, it should be verified that the ultimate bending capacity is larger than the flexural cracking moment. A capacity of 1,15 times the cracking moment is sufficient.

9.2.1.2 Other detailing arrangements

(1) In monolithic construction, even when simple supports have been assumed in design, the section at supports should be designed for a bending moment arising from partial fixity of at least β_1 of the maximum bending moment in the span.

Note 1: The value of β_1 for beams for use in a Country may be found in its National Annex. The recommended value is 0,15.

Note 2: The minimum area of longitudinal reinforcement section defined in 9.2.1.1 (1) applies.

(2) At intermediate supports of continuous beams, the total area of tension reinforcement A_s of a flanged cross-section should be spread over the effective width of flange (see 5.3.2). Part of it may be concentrated over the web width (See Figure 9.1).
Figure 9.1: Placing of tension reinforcement in flanged cross-section.

(3) Any compression longitudinal reinforcement (diameter ϕ) which is included in the resistance calculation should be held by transverse reinforcement with spacing not greater than 15ϕ.

9.2.1.3 Curtailment of longitudinal tension reinforcement

(1) Sufficient reinforcement should be provided at all sections to resist the envelope of the acting tensile force, including the effect of inclined cracks in webs and flanges.

(2) For members with shear reinforcement the additional tensile force, ΔF_{td}, should be calculated according to 6.2.3 (7). For members without shear reinforcement ΔF_{td} may be estimated by shifting the moment curve a distance $a_l = d$ according to 6.2.2 (5). This "shift rule" may also be used as an alternative for members with shear reinforcement, where:

$$a_l = z \, (\cot \theta - \cot \alpha)/2 \quad \text{(symbols defined in 6.2.3)} \tag{9.2}$$

The additional tensile force is illustrated in Figure 9.2.

(3) The resistance of bars within their anchorage lengths may be taken into account, assuming a linear variation of force, see Figure 9.2. As a conservative simplification this contribution may be ignored.

(4) The anchorage length of a bent-up bar which contributes to the resistance to shear should be not less than 1,3 l_{bd} in the tension zone and 0,7 l_{bd} in the compression zone. It is measured from the point of intersection of the axes of the bent-up bar and the longitudinal reinforcement.
$\boxed{A}$ - Envelope of $M_{Ed}/z + N_{Ed}$ $\boxed{B}$ - acting tensile force F_s $\boxed{C}$ - resisting tensile force F_{Rs}

Figure 9.2: Illustration of the curtailment of longitudinal reinforcement, taking into account the effect of inclined cracks and the resistance of reinforcement within anchorage lengths

9.2.1.4 Anchorage of bottom reinforcement at an end supports

(1) The area of bottom reinforcement provided at supports with little or no end fixity assumed in design, should be at least β_2 of the area of steel provided in the span.

> **Note:** The value of β_2 for beams for use in a Country may be found in its National Annex. The recommended value is 0,25.

(2) The tensile force to be anchored may be determined according to 6.2.3 (6) (members with shear reinforcement) including the contribution of the axial force if any, or according to the shift rule:

$$F_E = |V_{Ed}| \cdot a_l / z + N_{Ed} \tag{9.3}$$

where N_{Ed} is the axial force, to be added to or subtracted from the tensile force; a_l see 9.2.1.3 (2).

(3) The anchorage length is l_{bd} according to 8.4.4, measured from the line of contact between beam and support. Transverse pressure may be taken into account for direct support. See Figure 9.3.
a) Direct support: Beam supported by wall or column

b) Indirect support: Beam intersecting another supporting beam

Figure 9.3: Anchorage of bottom reinforcement at end supports

9.2.1.5 Anchorage of bottom reinforcement at intermediate supports

(1) The area of reinforcement given in 9.2.1.4 (1) applies.

(2) The anchorage length should not be less than 10ϕ (for straight bars) or not less than the diameter of the mandrel (for hooks and bends with bar diameters at least equal to 16 mm) or twice the diameter of the mandrel (in other cases) (see Figure 9.4 (a)). These minimum values are normally valid but a more refined analysis may be carried out in accordance with 6.6.

(3) The reinforcement required to resist possible positive moments (e.g. settlement of the support, explosion, etc.) should be specified in contract documents. This reinforcement should be continuous which may be achieved by means of lapped bars (see Figure 9.4 (b) or (c)).

a)   b)   c)
Figure 9.4: Anchorage at intermediate supports

9.2.2 Shear reinforcement

(1) The shear reinforcement should form an angle α of between 45° and 90° to the longitudinal axis of the structural element.

(2) The shear reinforcement may consist of a combination of:
  - links enclosing the longitudinal tension reinforcement and the compression zone (see Figure 9.5);
  - bent-up bars;

- cages, ladders, etc. which are cast in without enclosing the longitudinal reinforcement but are properly anchored in the compression and tension zones.

| A | Inner link alternatives | B | Enclosing link |
Figure 9.5: Examples of shear reinforcement

(3) Links should be effectively anchored. A lap joint on the leg near the surface of the web is permitted provided that the link is not required to resist torsion.

(4) At least β_3 of the necessary shear reinforcement should be in the form of links.

Note: The value of β_3 for use in a Country may be found in its National Annex. The recommended value is 0, 5.

(5) The ratio of shear reinforcement is given by Expression (9.4):

$$\rho_w = A_{sw} / (s . b_w . \sin\alpha) \tag{9.4}$$

where:

ρ_w is the shear reinforcement ratio

ρ_w should not be less than $\rho_{w,min}$

A_{sw} is the area of shear reinforcement within length s

s is the spacing of the shear reinforcement measured along the longitudinal axis of the member

b_w is the breadth of the web of the member

α is the angle between shear reinforcement and the longitudinal axis (see 9.2.2 (1))

Note: The value of $\rho_{w,min}$ for beams for use in a Country may be found in its National Annex. The recommended value is given Expression (9.5N)

$$\rho_{w,min} = (0{,}08\sqrt{f_{ck}})/f_{yk} \tag{9.5N}$$

(6) The maximum longitudinal spacing between shear assemblies should not exceed $s_{l,max}$.

Note: The value of $s_{l,max}$ for use in a Country may be found in its National Annex. The recommended value is given by Expression (9.6N)

$$s_{l,max} = 0{,}75d (1 + \cot\alpha) \tag{9.6N}$$

where α is the inclination of the shear reinforcement to the longitudinal axis of the beam.

(7) The maximum longitudinal spacing of bent-up bars should not exceed $s_{b,max}$:

Note: The value of $s_{b,max}$ for use in a Country may be found in its National Annex. The recommended value is given by Expression (9.7N)

$$s_{b,max} = 0,6\ d\ (1 + \cot \alpha) \tag{9.7N}$$

(8) The transverse spacing of the legs in a series of shear links should not exceed $s_{t,max}$:

Note: The value of $s_{t,max}$ for use in a Country may be found in its National Annex. The recommended value is given by Expression (9.8N)

$$s_{t,max} = 0,75d \le 600 \text{ mm} \tag{9.8N}$$

9.2.3 Torsion reinforcement

(1) The torsion links should be closed and be anchored by means of laps or hooked ends, see Figure 9.6, and should form an angle of 90° with the axis of the structural element.

a1)   **a2)**   **a3)**

a) recommended shapes   **b) not recommended shape**
Note: The second alternative for a2) (lower sketch) should have a full lap length along the top.

Figure 9.6: Examples of shapes for torsion links

(2) The provisions of 9.2.2 (5) and (6) are generally sufficient to provide the minimum torsion links required.

(3) The longitudinal spacing of the torsion links should not exceed u / 8 (see 6.3.2, Figure 6.11, for the notation), or the requirement in 9.2.2 (6) or the lesser dimension of the beam cross-section.

(4) The longitudinal bars should be so arranged that there is at least one bar at each corner, the others being distributed uniformly around the inner periphery of the links, with a spacing not greater than 350 mm.

9.2.4 Surface reinforcement

(1) It may be necessary to provide surface reinforcement either to control cracking or to ensure adequate resistance to spalling of the cover.

Note: Detailing rules for surface reinforcement are given in Informative Annex J.

9.2.5 Indirect supports

(1) Where a beam is supported by a beam instead of a wall or column, reinforcement should be provided and designed to resist the mutual reaction. This reinforcement is in addition to that required for other reasons. This rule also applies to a slab not supported at the top of a beam.

(2) The supporting reinforcement between two beams should consist of links surrounding the principal reinforcement of the supporting member. Some of these links may be distributed outside the volume of the concrete, which is common to the two beams, (see Figure 9.7).
A supporting beam with height h_1 B supported beam with height h_2 ($h_1 \geq h_2$)

Figure 9.7: Placing of supporting reinforcement in the intersection zone of two beams (plan view)

9.3   Solid slabs

(1) This section applies to one-way and two-way solid slabs for which b and l_{eff} are not less than $5h$ (see 5.3.1).

9.3.1 Flexural reinforcement

9.3.1.1 General

(1) For the minimum and the maximum steel percentages in the main direction 9.2.1.1 (1) and (3) apply.

> **Note:** In addition to Note 2 of 9.2.1.1 (1), for slabs where the risk of brittle failure is small, $A_{s,min}$ may be taken as 1,2 times the area required in ULS verification.

(2) Secondary transverse reinforcement of not less than 20% of the principal reinforcement should be provided in one way slabs. In areas near supports transverse reinforcement to principal top bars is not necessary where there is no transverse bending moment.

(3) The spacing of bars should not exceed $s_{max,slabs}$.

> **Note;** The value of $s_{max,slabs}$ for use in a Country may be found in its National Annex. The recommended value is:
> - for the principal reinforcement, $3h \leq 400$ mm, where h is the total depth of the slab;

- for the secondary reinforcement, $3,5h \le 450$ mm .

In areas with concentrated loads or areas of maximum moment those provisions become respectively:
- for the principal reinforcement, $2h \le 250$ mm
-   for the secondary reinforcement, $3h \le 400$ mm.

(4) The rules given in 9.2.1.3 (1) to (3), 9.2.1.4 (1) to (3) and 9.2.1.5 (1) to (2) also apply but with $a_l = d$.

9.3.1.2 Reinforcement in slabs near supports

(1) In simply supported slabs, half the calculated span reinforcement should continue up to the support and be anchored therein in accordance with 8.4.4.

> **Note:** Curtailment and anchorage of reinforcement may be carried out according to 9.2.1.3, 9.2.1.4 and 9.2.1.5.

(2) Where partial fixity occurs along an edge of a slab, but is not taken into account in the analysis, the top reinforcement should be capable of resisting at least 25% of the maximum moment in the adjacent span. This reinforcement should extend at least 0,2 times the length of the adjacent span, measured from the face of the support. It should be continuous across internal supports and anchored at end supports. At an end support the moment to be resisted may be reduced to 15% of the maximum moment in the adjacent span.

9.3.1.3 Corner reinforcement

(1) If the detailing arrangements at a support are such that lifting of the slab at a corner is restrained, suitable reinforcement should be provided.

9.3.1.4 Reinforcement at the free edges

(1) Along a free (unsupported) edge, a slab should normally contain longitudinal and transverse reinforcement, generally arranged as shown in Figure 9.8.

(2) The normal reinforcement provided for a slab may act as edge reinforcement.
Figure 9.8: Edge reinforcement for a slab

9.3.2 Shear reinforcement

(1) A slab in which shear reinforcement is provided should have a depth of at least 200 mm.

(2) In detailing the shear reinforcement, the minimum value and definition of reinforcement ratio in 9.2.2 apply, unless modified by the following.

(3) In slabs, if $|V_{Ed}| \le 1/3 \; V_{Rd,max}$, (see 6.2), the shear reinforcement may consist entirely of bent-up bars or of shear reinforcement assemblies.

(4) The maximum longitudinal spacing of successive series of links is given by:

$$s_{max} = 0,75d(1+\cot\alpha)$$ (9.9)

where α is the inclination of the shear reinforcement.

The maximum longitudinal spacing of bent-up bars is given by:
$$s_{max} = d.$$ (9.10)

(5) The maximum transverse spacing of shear reinforcement should not exceed 1,5d.

9.4 Flat slabs

9.4.1 Slab at internal columns

(1) The arrangement of reinforcement in flat slab construction should reflect the behaviour under working conditions. In general this will result in a concentration of reinforcement over the columns.

(2) At internal columns, unless rigorous serviceability calculations are carried out, top reinforcement of area 0,5 A_t should be placed in a width equal to the sum of 0,125 times the panel width on either side of the column. A_t represents the area of reinforcement required to resist the full negative moment from the sum of the two half panels each side of the column.

(3) Bottom reinforcement ($\geq$ 2 bars) in each orthogonal direction should be provided at internal columns and this reinforcement should pass through the column.

9.4.2 Slab at edge and corner columns

(1) Reinforcement perpendicular to a free edge required to transmit bending moments from the slab to an edge or corner column should be placed within the effective width b_e shown in Figure 9.9.

Note: y can be $> c_y$

Note: z can be $> c_z$ and y can be $> c_y$

$\boxed{A}$ Slab edge
a) Edge column   **b) Corner column**

Note: y is the distance from the edge of the slab to the innermost face of the column.

Figure 9.9: Effective width, b_e, of a flat slab

9.4.3 Punching shear reinforcement

(1) Where punching shear reinforcement is required (see 6.4) it should be placed between the loaded area/column and *kd* inside the control perimeter at which shear reinforcement is no longer required. It should be provided in at least two perimeters of link legs (see Figure 9.10). The spacing of the link leg perimeters should not exceed 0,75*d*.

The spacing of link legs around a perimeter should not exceed 1,5*d* within the first control perimeter (2*d* from loaded area), and should not exceed 2*d* for perimeters outside the first control perimeter where that part of the perimeter is assumed to contribute to the shear capacity (see Figure 6.22).

For bent down bars as arranged in Figure 9.10 b) one perimeter of link legs may be considered sufficient.

A - outer control perimeter requiring shear reinforcement

B - first control perimeter not requiring shear reinforcement

a) Spacing of links   **b) Spacing of bent-up bars**
Figure 9.10: Punching shear reinforcement

Note: See 6.4.5 (4) for the value of *k*.

(2) Where shear reinforcement is required the area of a link leg (or equivalent), $A_{sw,min}$, is given by Expression (9.11).

$$A_{sw,min} \cdot (1{,}5 \cdot \sin\alpha + \cos\alpha)/(s_r \cdot s_t) \geq 0{,}08 \cdot \sqrt{(f_{ck})}/f_{yk} \qquad (9.11)$$

where :

  α is the angle between the shear reinforcement and the main steel (i.e. for vertical links $\alpha = 90°$ and $\sin \alpha = 1$)
  s_r is the spacing of shear links in the radial direction
  s_t is the spacing of shear links in the tangential direction
  f_{ck} is in MPa

The vertical component of only those prestressing tendons passing within a distance of 0.5d of the column may be included in the shear calculation.

(3) Bent-up bars passing through the loaded area or at a distance not exceeding 0,25d from this area may be used as punching shear reinforcement (see Figure 9.10 b), top).

(4) The distance between the face of a support, or the circumference of a loaded area, and the nearest shear reinforcement taken into account in the design should not exceed d/2. This distance should be taken at the level of the tensile reinforcement. If only a single line of bent-up bars is provided, their slope may be reduced to 30°.

9.5   Columns

9.5.1 General

(1) This clause deals with columns for which the larger dimension h is not greater than 4 times the smaller dimension b.

9.5.2 Longitudinal reinforcement

(1) Longitudinal bars should have a diameter of not less than ϕ_{min}.

> **Note:** The value of ϕ_{min} for use in a Country may be found in its National Annex. The recommended value is 8 mm.

(2) The total amount of longitudinal reinforcement should not be less than $A_{s,min}$.

> **Note:** The value of $A_{s,min}$ for use in a Country may be found in its National Annex. The recommended value is given by Expression (9.12N)

$$A_{s,min} = \frac{0,10 \ N_{Ed}}{f_{yd}} \ \text{ or } 0,002 \ A_c \text{ whichever is the greater} \tag{9.12N}$$

where:
   f_{yd} is the design yield strength of the reinforcement
   N_{Ed} is the design axial compression force

(3) The area of longitudinal reinforcement should not exceed $A_{s,max}$.

> **Note:** The value of $A_{s,max}$ for use in a Country may be found in its National Annex. The recommended value is 0,04 A_c outside lap locations unless it can be shown that the integrity of concrete is not affected, and that the full strength is achieved at ULS. This limit should be increased to 0,08 A_c at laps.

(4) For columns having a polygonal cross-section, at least one bar should be placed at each corner. The number of longitudinal bars in a circular column should not be less than four.

9.5.3 Transverse reinforcement

(1) The diameter of the transverse reinforcement (links, loops or helical spiral reinforcement) should not be less than 6 mm or one quarter of the maximum diameter of the longitudinal bars, whichever is the greater. The diameter of the wires of welded mesh fabric for transverse reinforcement should not be less than 5 mm.

(2) The transverse reinforcement should be anchored adequately.

(3) The spacing of the transverse reinforcement along the column should not exceed $s_{cl,tmax}$

Note: The value of $s_{cl,tmax}$ for use in a Country may be found in its National Annex. The recommended value is the least of the following three distances:
- 20 times the minimum diameter of the longitudinal bars
- the lesser dimension of the column
- 400 mm

(4) The maximum spacing required in (3) should be reduced by a factor 0,6:

(i) in sections within a distance equal to the larger dimension of the column cross-section above or below a beam or slab;

(ii) near lapped joints, if the maximum diameter of the longitudinal bars is greater than 14 mm. A minimum of 3 bars evenly placed in the lap length is required.

(5) Where the direction of the longitudinal bars changes, (e.g. at changes in column size), the spacing of transverse reinforcement should be calculated, taking account of the lateral forces involved. These effects may be ignored if the change of direction is less than or equal to 1 in 12.

(6) Every longitudinal bar or bundle of bars placed in a corner should be held by transverse reinforcement. No bar within a compression zone should be further than 150 mm from a restrained bar.

9.6 Walls

9.6.1 General

(1) This clause refers to reinforced concrete walls with a length to thickness ratio of 4 or more and in which the reinforcement is taken into account in the strength analysis. The amount and proper detailing of reinforcement may be derived from a strut-and-tie model (see 6.5). For walls subjected predominantly to out-of-plane bending the rules for slabs apply (see 9.3).

9.6.2 Vertical reinforcement

(1) The area of the vertical reinforcement should lie between $A_{s,vmin}$ and $A_{s,vmax}$.

Note 1: The value of $A_{s,vmin}$ for use in a Country may be found in its National Annex. The recommended value is 0,002 A_c.

Note 2: The value of $A_{s,vmax}$ for use in a Country may be found in its National Annex. The recommended value is 0,04 A_c outside lap locations unless it can be shown that the concrete integrity is not affected and that the full strength is achieved at ULS. This limit may be doubled at laps.

(2) Where the minimum area of reinforcement, $A_{s,vmin}$, controls in design, half of this area should be located at each face.

(3) The distance between two adjacent vertical bars shall not exceed 3 times the wall thickness or 400 mm whichever is the lesser.

9.6.3 Horizontal reinforcement

(1) Horizontal reinforcement running parallel to the faces of the wall (and to the free edges) should be provided at each surface. It should not be less than $A_{s,hmin}$.

Note: The value of $A_{s,hmin}$ for use in a Country may be found in its National Annex. The recommended value is either 25% of the vertical reinforcement or 0,001 A_c, whichever is greater.

(2) The spacing between two adjacent horizontal bars should not be greater than 400 mm.

9.6.4 Transverse reinforcement

(1) In any part of a wall where the total area of the vertical reinforcement in the two faces exceeds 0,02 A_c, transverse reinforcement in the form of links should be provided in accordance with the requirements for columns (see 9.5.3). The large dimension referred to in 9.5.3 (4) (i) need not be taken greater than 4 x thickness of wall.

(2) Where the main reinforcement is placed nearest to the wall faces, transverse reinforcement should also be provided in the form of links with at least of 4 per m^2 of wall area.

> **Note:** Transverse reinforcement need not be provided where welded wire mesh and bars of diameter $\phi \leq 16$ mm are used with concrete cover larger than 2ϕ,

9.7   Deep beams

(1) Deep beams (for definition see 5.3.1 (3)) should normally be provided with an orthogonal reinforcement mesh near each face, with a minimum of $A_{s,dbmin}$.

> **Note:** The value of $A_{s,dbmin}$ for use in a Country may be found in its National Annex. The recommended value is 0,1% but not less than 150 mm²/m in each face and each direction.

(2) The distance between two adjacent bars of the mesh should not exceed the lesser of twice the deep beam thickness or 300 mm.

(3) Reinforcement, corresponding to the ties considered in the design model, should be fully anchored for equilibrium in the node, see 6.5.4, by bending the bars, by using U-hoops or by anchorage devices, unless a sufficient length is available between the node and the end of the beam permitting an anchorage length of l_{bd}.

9.8   Foundations

9.8.1 Pile caps

(1)   The distance from the outer edge of the pile to the edge of the pile cap should be such that the tie forces in the pile cap can be properly anchored. The expected deviation of the pile on site should be taken into account.

(2) Reinforcement in a pile cap should be calculated either by using strut-and-tie or flexural methods as appropriate.

(3) The main tensile reinforcement to resist the action effects should be concentrated in the stress zones between the tops of the piles. A minimum bar diameter ϕ_{min} should be provided. If the area of this reinforcement is at least equal to the minimum reinforcement, evenly distributed bars along the bottom surface of the member may be omitted. Also the sides and the top surface of the member may be unreinforced if there is no risk of tension developing in these parts of the member.

> **Note:** The value of ϕ_{min} for use in a Country may be found in its National Annex. The recommended value is 8 mm.

(4) Welded transverse bars may be used for the anchorage of the tension reinforcement. In this case the transverse bar may be considered to be part of the transverse reinforcement in the anchorage zone of the reinforcement bar considered.

(5) The compression caused by the support reaction from the pile may be assumed to spread at 45 degree angles from the edge of the pile (see Figure 9.11). This compression may be taken into account when calculating the anchorage length.
$\boxed{A}$ - compressed area

Figure 9.11: Compressed area increasing the anchorage capacity

9.8.2 Column and wall footings

9.8.2.1 General

(1) The main reinforcement should be anchored in accordance with the requirements of 8.4 and 8.5. A minimum bar diameter ϕ_{min} should be provided. In footings the design model shown in 9.8.2.1 may be used.

> **Note:** The value of ϕ_{min} for use in a Country may be found in its National Annex. The recommended value is 8 mm.

(2) The main reinforcement of circular footings may be orthogonal and concentrated in the middle of the footing for a width of 50% $\pm$ 10% of the diameter of the footing, see Figure 9.12. In this case the unreinforced parts of the element should be considered as plain concrete for design purposes.
Figure 9.12: Orthogonal reinforcement in circular spread footing on soil

(3) If the action effects cause tension at the upper surface of the footing, the resulting tensile stresses should be checked and reinforced as necessary.

9.8.2.2 Anchorage of bars

(1)   The tensile force in the reinforcement is determined from equilibrium conditions, taking into account the effect of inclined cracks, see Figure 9.13. The tensile force F_s at a location x should be anchored in the concrete within the same distance x from the edge of the footing.
Figure 9.13: Model for tensile force with regard to inclined cracks

(2) The tensile force to be anchored is given by:

$$F_s = R \cdot z_e/z_i \tag{9.13}$$

where:
  R is the resultant of ground pressure within distance x
  z_e is the external lever arm, i.e. distance between R and the vertical force N_{Ed}
  N_{Ed} is the vertical force corresponding to total ground pressure between sections A and B
  z_i is the internal lever arm, i.e. distance between the reinforcement and the horizontal force F_c
  F_c is the compressive force corresponding to maximum tensile force $F_{s,max}$

(3) Lever arms z_e and z_i may be determined with regard to the necessary compression zones for N_{Ed} and F_c respectively. As simplifications, z_e may be determined assuming $e = 0,15b$, see Figure 9.13 and z_i may be taken as $0,9d$.

(4) The available anchorage length for straight bars is denoted l_b in Figure 9.13. If this length is not sufficient to anchor F_s, bars may either be bent up to increase the available length or be provided with end anchorage devices.

(5) For straight bars without end anchorage the minimum value of x is the most critical. As a simplification $x_{min} = h/2$ may be assumed. For other types of anchorage, higher values of x may be more critical.

9.8.3 Tie beams

(1) Tie beams may be used to eliminate the eccentricity of loading of the foundations. The beams should be designed to resist the resulting bending moments and shear forces. A minimum bar diameter ϕ_{min} for the reinforcement resisting bending moments should be provided.

> **Note:** The value of ϕ_{min} for use in a Country may be found in its National Annex. The recommended value is 8 mm.

(2) Tie beams should also be designed for a minimum downward load of q_1 if the action of compaction machinery can cause effects to the tie beams.

> **Note:** The value of q_1 for use in a Country may be found in its National Annex. The recommended value is 10 kN/m.

9.8.4 Column footing on rock

(1) Adequate transverse reinforcement should be provided to resist the splitting forces in the footing, when the ground pressure in the ultimate states exceeds q_2. This reinforcement may be distributed uniformly in the direction of the splitting force over the height h (see Figure 9.14). A minimum bar diameter, ϕ_{min}, should be provided.

> **Note:** The values of q_2 and of ϕ_{min} for use in a Country may be found in its National Annex. The recommended values of q_2 is 5 MPa and of ϕ_{min} is 8 mm.

(2) The splitting force, F_s, may be calculated as follows (see Figure 9.14) :

$$F_s = 0{,}25 \, (1 - c/h)N_{Ed} \tag{9.14}$$

Where h is the lesser of b and H

a) footing with $h \geq H$ b) section   c) footing with $h < H$
Figure 9.14: Splitting reinforcement in footing on rock

9.8.5 Bored piles

(1) The following clauses apply for reinforced bored piles. For unreinforced bored piles see Section 12.

(2) In order to allow the free flow of concrete around the reinforcement it is of primary importance that reinforcement, reinforcement cages and any attached inserts are detailed such that the flow of concrete is not adversely affected.

(3) Bored piles with diameters not exceeding h_1 should be provided with a minimum longitudinal reinforcement area $A_{s,bpmin}$.

> **Note:** The values of h_1 and $A_{s,bpmin}$ for use in a Country may be found in its National Annex. The recommended value of h_1 is 600 mm and of $A_{s,bpmin}$ is given in Table 9.6N. This reinforcement should be distributed along the periphery of the section.

Table 9.6N: Recommended minimum longitudinal reinforcement area in cast-in-place bored piles

Pile cross-section: A_c	Minimum area of longitudinal reinforcement: $A_{S,bpmin}$
$A_c \leq 0,5$ m²	$A_S \geq 0,005 \cdot A_c$
$0,5$ m² $< A_c \leq 1,0$ m²	$A_S \geq 25$ cm^2
$A_c > 1,0$ m²	$A_S \geq 0,0025 \cdot A_c$

> The minimum diameter for the longitudinal bars should not be less than 16 mm. Piles should have at least 6 longitudinal bars. The clear distance between bars should not exceed 200 mm measured along the periphery of the pile.

(4) For the detailing of longitudinal and transverse reinforcement in bored piles, see EN 1536.

9.9   Regions with discontinuity in geometry or action

(1)   D-regions should normally be designed with strut-and-tie models according to section 6.5 and detailed according to the rules given in Section 8.

> **Note:** Further information is given in Annex J.

(2)P   The reinforcement, corresponding to the ties, shall be fully anchored by an anchorage of l_{bd} according to 8.4.

9.10   Tying systems

9.10.1 General

(1)P Structures which are not designed to withstand accidental actions shall have a suitable tying system, to prevent progressive collapse by providing alternative load paths after local damage. The following simple rules are deemed to satisfy this requirement.

(2) The following ties should be provided:
   a) peripheral ties
   b) internal ties
   c) horizontal column or wall ties
   d) where required, vertical ties, particularly in panel buildings.

(3)   Where a building is divided by expansion joints into structurally independent sections, each section should have an independent tying system.

(4) In the design of the ties the reinforcement may be assumed to be acting at its characteristic strength and capable of carrying tensile forces defined in the following clauses.

(5) Reinforcement provided for other purposes in columns, walls, beams and floors may be regarded as providing part of or the whole of these ties.

9.10.2 Proportioning of ties

9.10.2.1 General

(1) Ties are intended as a minimum and not as an additional reinforcement to that required by structural analysis.

9.10.2.2 Peripheral ties

(1) At each floor and roof level an effectively continuous peripheral tie within 1,2 m from the edge should be provided. The tie may include reinforcement used as part of the internal tie.

(2) The peripheral tie should be capable of resisting a tensile force:

$$F_{tie,per} = l_i \cdot q_1 \leq q_2 \tag{9.15}$$

where:
  $F_{tie,per}$ tie force (here: tension)
  l_i length of the end-span

Note: Values of q_1 and q_2 for use in a Country may be found in its National Annex. The recommended value of q_1 is 10 kN/m and of q_2 is 70 kN.

(3)   Structures with internal edges (e.g. atriums, courtyards, etc.) should have peripheral ties in the same way as external edges which shall be fully anchored.

9.10.2.3 Internal ties

(1) These ties should be at each floor and roof level in two directions approximately at right angles. They should be effectively continuous throughout their length and should be anchored to the peripheral ties at each end, unless continuing as horizontal ties to columns or walls.

(2) The internal ties may, in whole or in part, be spread evenly in the slabs or may be grouped at or in beams, walls or other appropriate positions. In walls they should be within 0,5 m from the top or bottom of floor slabs, see Figure 9.15.

(3) In each direction, internal ties should be capable of resisting a design value of tensile force $F_{tie,int}$ (in kN per metre width):

Note: Values of $F_{tie,int}$ for use in a Country may be found in its National Annex. The recommended value is 20 kN/m.

 (4) In floors without screeds where ties cannot be distributed across the span direction, the transverse ties may be grouped along the beam lines. In this case the minimum force on an internal beam line is:

$$F_{tie} = (l_1 + l_2)/2 \cdot q_3 \leq q_4 \qquad\qquad (9.16)$$

where:

l_1, l_2 are the span lengths (in m) of the floor slabs on either side of the beam (see Figure 9.15)

Note: Values of q_3 and q_4 for use in a Country may be found in its National Annex. The recommended value of q_3 is 20 kN/m and of q_4 is 70 kN.

(5) Internal ties should be connected to peripheral ties such that the transfer of forces is assured.

A - peripheral tie   B - internal tie   C - horizontal column or wall tie
Figure 9.15: Ties for Accidental Actions

9.10.2.4 Horizontal ties to columns and/or walls

(1) Edge columns and walls should be tied horizontally to the structure at each floor and roof level.

(2) The ties should be capable of resisting a tensile force $f_{tie,fac}$ per metre of the façade. For columns the force need not exceed $F_{tie,col}$.

Note: Values of $f_{tie,fac}$ and $F_{tie,col}$ for use in a Country may be found in its National Annex. The recommended value of $f_{tie,fac}$ is 20 kN/m and of $F_{tie,col}$ is 150 kN.

(3) Corner columns should be tied in two directions. Steel provided for the peripheral tie may be used as the horizontal tie in this case.

9.10.2.5 Vertical ties

(1) In panel buildings of 5 storeys or more, vertical ties should be provided in columns and/or walls to limit the damage of collapse of a floor in the case of accidental loss of the column or wall below. These ties should form part of a bridging system to span over the damaged area.

(2) Normally, continuous vertical ties should be provided from the lowest to the highest level, capable of carrying the load in the accidental design situation, acting on the floor above the column/wall accidentally lost. Other solutions e.g. based on the diaphragm action of remaining wall elements and/or on membrane action in floors, may be used if equilibrium and sufficient deformation capacity can be verified.

(3) Where a column or wall is supported at its lowest level by an element other than a foundation (e.g. beam or flat slab) accidental loss of this element should be considered in the design and a suitable alternative load path should be provided.

9.10.3 Continuity and anchorage of ties

(1)P Ties in two horizontal directions shall be effectively continuous and anchored at the perimeter of the structure.

(2) Ties may be provided wholly within the insitu concrete topping or at connections of precast members. Where ties are not continuous in one plane, the bending effects resulting from the eccentricities should be considered.

(3) Ties should not normally be lapped in narrow joints between precast units. Mechanical anchorage should be used in these cases.

SECTION 10   ADDITIONAL RULES FOR PRECAST CONCRETE ELEMENTS AND STRUCTURES

10.1   General

(1)P The rules in this section apply to buildings made partly or entirely of precast concrete elements, and are supplementary to the rules in other sections. Additional matters related to detailing, production and assembly are covered by specific product standards.

> **Note:** Headings are numbered 10 followed by the number of the corresponding main section. Headings of lower level are numbered consecutively, without connection to sub-headings in previous sections.

10.1.1   Special terms used in this section

Precast element: element manufactured in a factory or a place other than the final position in the structure, protected from adverse weather conditions

Precast product: precast element manufactured in compliance with a specific CEN standard

Composite element: element comprising in-situ and precast concrete with or without reinforcement connectors

Rib and block floor: consists of precast ribs (or beams) with an infill between them, made of blocks, hollow clay pots or other forms of permanent shuttering, with or without an in-situ topping

Diaphragm: plane member which is subjected to in-plane forces; may consist of several precast units connected together

Tie: in the context of precast structures, a ties is a tensile member, effectively continuous, placed in a floor, wall or column

Isolated precast member: member for which, in case of failure, no secondary means of load transfer is available

Transient situation in precast concrete construction includes
   - demoulding
   - transport to the storage yard
   - storage (support and load conditions)
   - transport to site
   - erection (hoisting)
   - construction (assembly)

10.2   Basis of design, fundamental requirements

(1)P In design and detailing of precast concrete elements and structures, the following shall be considered specifically:

   - transient situations (see 10.1.1)
   - bearings; temporary and permanent
   - connections and joints between elements

(2) Where relevant, dynamic effects in transient situations should be taken into account. In the absence of an accurate analysis, static effects may be multiplied by an appropriate factor (see also product standards for specific types of precast products).

(3) Where required, mechanical devices should be detailed in order to allow ease of assembly, inspection and replacement.

10.3   Materials

10.3.1 Concrete

10.3.1.1 Strength

(1) For precast products in continuous production, subjected to an appropriate quality control system according to the product standards, with the concrete tensile strength tested, a statistical analysis of test results may be used as a basis for the evaluation of the tensile strength that is used for serviceability limit states verifications, as an alternative to Table 3.1.

(2) Intermediate strength classes within Table 3.1 may be used.

(3) In the case of heat curing of precast concrete elements, the compressive strength of concrete at an age t before 28 days, $f_{cm}(t)$, may be estimated from Expression (3.3) in which the concrete age t is substituted by the temperature adjusted concrete age obtained by Expression (B.10) of Annex B.

   Note: The coefficient $\beta_{cc}(t)$ should be limited to 1.

For the effect of heat curing Expression (10.1) may be used:

$$f_{cm}(t) = f_{cmp} + \frac{f_{cm} - f_{cmp}}{\log(28 - t_p + 1)}\log(t - t_p + 1) \tag{10.1}$$

   Where f_{cmp} is the mean compressive strength after the heat curing (i.e. at the release of the prestress), measured by testing of samples at the time t_p ($t_p < t$), that went through the same heat treatment with the precast elements.

10.3.1.2 Creep and shrinkage

(1) In the case of a heat curing of the precast concrete elements, it is permitted to estimate the values of creep deformations according to the maturity function, Expression (B.10) of Annex B.

(2) In order to calculate the creep deformations, the age of concrete at loading t_0 (in days) in Expression (B.5) should be replaced by the equivalent concrete age obtained by Expressions (B.9) and (B.10) of Annex B.

(3) In precast elements subjected to heat curing it may be assumed that:
    a) the shrinkage strain is not significant during heat curing and
    b) autogenous shrinkage strain is negligible.

10.3.2 Prestressing steel

10.3.2.2 Technological properties of prestressing steel

(1)P   For pre-tensioned members, the effect on the relaxation losses of increasing the temperature while curing the concrete, shall be considered.

Note: The relaxation is accelerated during the application of a thermal curing when a thermal strain is introduced at the same time. Finally, the relaxation rate is reduced at the end of the treatment.

(2) An equivalent time t_{eq} should be added to the time after tensioning t in the relaxation time functions, given in 3.3.2(7), to cater for the effects of the heat treatment on the prestress loss due to the relaxation of the prestressing steel. The equivalent time can be estimated from Expression (10.2):

$$t_{eq} = \frac{1{,}14^{T_{max}-20}}{T_{max}-20} \sum_{i=1}^{n} \left(T_{(\Delta t_i)} - 20 \right) \Delta t_i \tag{10.2}$$

where
t_{eq} is the equivalent time (in hours)
$T_{(\Delta ti)}$ is the temperature (in °C) during the time interval Δt_i
T_{max} is the maximum temperature (in °C) during the heat treatment

10.5   Structural analysis

10.5.1 General

(1)P The analysis shall account for:
- the behaviour of the structural units at all stages of construction using the appropriate geometry and properties for each stage, and their interaction with other elements (e.g. composite action with in-situ concrete, other precast units);
- the behaviour of the structural system influenced by the behaviour of the connections between elements, with particular regard to actual deformations and strength of connections;
- the uncertainties influencing restraints and force transmission between elements arising from deviations in geometry and in the positioning of units and bearings.

(2) Beneficial effects of horizontal restraint caused by friction due to the weight of any supported element may only be used in non seismic zones (using $\gamma_{G,inf}$) and where:
- the friction is not solely relied upon for overall stability of the structure;
- the bearing arrangements preclude the possibility of accumulation of irreversible sliding of the elements, such as caused by uneven behaviour under alternate actions (e.g. cyclic thermal effects on the contact edges of simply supported elements);
- the possibility of significant impact loading is eliminated

(3) The effects of horizontal movements should be considered in design with respect to the resistance of the structure and the integrity of the connections.

10.5.2 Losses of prestress

(1) In the case of heat curing of precast concrete elements, the lessening of the tension in the tendons and the restrained dilatation of the concrete due to the temperature, induce a specific thermal loss ΔP_θ. This loss may be estimated by the Expression (10.3):

$$\Delta P_\theta = 0{,}5 \, A_p \, E_p \, \alpha_c \, (T_{max} - T_o) \tag{10.3}$$

Where
A_p is the cross-section of tendons
E_p is the elasticity modulus of tendons

α_c is the linear coefficient of thermal expansion for concrete (see 3.1.2)

$T_{max} - T_0$ is the difference between the maximum and initial temperature in the concrete near the tendons, in °C

Note: Any loss of prestress, ΔP_θ, caused by elongation due to heat curing may be ignored if preheating of the tendons is applied.

10.9   Particular rules for design and detailing

10.9.1 Restraining moments in slabs

(1) Restraining moments may be resisted by top reinforcement placed in the topping or in plugs in open cores of hollow core units. In the former case the horizontal shear in the connection should be checked according to 6.2.5. In the latter case the transfer of force between the in situ concrete plug and the hollow core unit should be verified according to 6.2.5. The length of the top reinforcement should be in accordance with 9.2.1.3.

(2) Unintended restraining effects at the supports of simply supported slabs should be considered by special reinforcement and/or detailing.

10.9.2 Wall to floor connections

(1) In wall elements installed over floor slabs, reinforcement should normally be provided for possible eccentricities and concentrations of the vertical load at the end of the wall. For floor elements see 10.9.1 (2).

(2) No specific reinforcement is required provided the vertical load per unit length is $\leq 0,5h.f_{cd}$, where h is the wall thickness, see Figure 10.1. The load may be increased to $0,6h.f_{cd}$ with reinforcement according to Figure 10.1, having diameter $\phi \geq 6$ mm and spacing s not greater than the lesser of h and 200 mm. For higher loads, reinforcement should be designed according to (1). A separate check should be made for the lower wall.
Figure 10.1: Example of reinforcement in a wall over a connection between two floor slabs.

10.9.3 Floor systems

(1)P The detailing of floor systems shall be consistent with assumptions in analysis and design. Relevant product standards shall be considered.

(2)P Where transverse load distribution between adjacent units has been taken into account, appropriate shear connection shall be provided.

(3)P The effects of possible restraints of precast units shall be considered, even if simple supports have been assumed in design.

(4) Shear transfer in connections may be achieved in different ways. Three main types of connections shown in Figure 10.2.

(5) Transverse distribution of loads should be based on analysis or tests, taking into account possible load variations between precast elements. The resulting shear force between floor units should be considered in the design of connections and adjacent parts of elements (e.g. outside ribs or webs).

For floors with uniformly distributed load, and in the absence of a more accurate analysis, this shear force per unit length may be taken as:

$$v_{Ed} = q_{Ed} \cdot b_e / 3 \qquad\qquad (10.4)$$

where:
q_{Ed} is the design value of variable load (kN/m^2)
b_e is the width of the element

a) **concreted or grouted connections**

b) **welded or bolted connections (this shows *one* type of *welded* connection as an example)**

c) **reinforced topping. (vertical reinforcement connectors to topping may be required to ensure shear transfer at ULS)**
Figure 10.2: Examples of connections for shear transfer

(6) Where precast floors are assumed to act as diaphragms to transfer horizontal loads to bracing units, the following should be considered:
-    the diaphragm should form part of a realistic structural model, taking into account the deformation compatibility with bracing units,
-    the effects of horizontal deformations should be taken into account for all parts of the structure involved in the transfer of horizontal loads,
-    the diaphragm should be reinforced for the tensile forces assumed in the structural model,
-    stress concentrations at openings and connections should be taken into account in the detailing of reinforcement.

(7) Transverse reinforcement for shear transfer across connections in the diaphragm may be concentrated along supports, forming ties consistent with the structural model. This reinforcement may be placed in the topping, if it exists.

(8) Precast units with a topping of at least 40 mm may be designed as composite members, if shear in the interface is verified according to 6.2.5. The precast unit should be checked at all stages of construction, before and after composite action has become effective.

(9) Transverse reinforcement for bending and other action effects may lie entirely within the topping. The detailing should be consistent with the structural model, e.g. if two-way spanning is assumed.

(10) Webs or ribs in isolated slab units (i.e. units which are not connected for shear transfer) should be provided with shear reinforcement as for beams.

(11) Floors with precast ribs and blocks without topping may be analysed as solid slabs, if the insitu transverse ribs are provided with continuous reinforcement through the precast longitudinal ribs and at a spacing s_T according to Table 10.1.

(12) In diaphragm action between precast slab elements with concreted or grouted connections, the average longitudinal shear stress v_{Rdi} should be limited to 0,1 MPa for very smooth surfaces, and to 0,15 MPa for smooth and rough surfaces. See 6.2.5 for definition of surfaces.

Table 10.1: Maximum spacing of transverse ribs, s_T for the analysis of floors with ribs and block as solid slabs. s_L = spacing of longitudinal ribs, l_L = length (span) of longitudinal ribs, h = thickness of ribbed floor

Type of imposed loading	$s_L \leq l_L/8$	$s_L > l_L/8$
Residential, snow	not required	$s_T \leq 12\ h$
Other	$s_T \leq 10\ h$	$s_T \leq 8\ h$

10.9.4 Connections and supports for precast elements

10.9.4.1 Materials

(1)P Materials used for connections shall be:
- stable and durable for the design working life of the structure
- chemically and physically compatible
- protected against adverse chemical and physical influences
- fire resistant to match the fire resistance of the structure.

(2)P Supporting pads shall have strength and deformation properties in accordance with the design assumptions.

(3)P Metal fastenings for claddings, other than in environmental classes X0 and XC1 (Table 4.1) and not protected against the environment, shall be of corrosion resistant material. If inspection is possible, coated material may also be used.

(4)P Before undertaking welding, annealing or cold forming the suitability of the material shall be verified.

10.9.4.2 General rules for design and detailing of connections

(1)P Connections shall be able to resist action effects consistent with design assumptions, to accommodate the necessary deformations and ensure robust behaviour of the structure.

(2)P Premature splitting or spalling of concrete at the ends of elements shall be prevented, taking into account

- relative movements between elements
- deviations
- assembly requirements
- ease of execution
- ease of inspection

(3) Verification of resistance and stiffness of connections may be based on analysis, possibly assisted by testing (for design assisted by testing, see EN 1990, Annex D). Imperfections should be taken into account. Design values based on tests should allow for unfavourable deviations from testing conditions.

10.9.4.3 Connections transmitting compressive forces

(1) Shear forces may be ignored in compression connections if they are less than 10% of the compressive force.

(2) For connections with bedding materials like mortar, concrete or polymers, relative movement between the connected surfaces should be prevented during hardening of the material.

(3) Connections without bedding material (dry connections) should only be used where an appropriate quality of workmanship can be achieved. The average bearing stress between plane surfaces should not exceed $0,3$ f_{cd}. Dry connections including curved (convex) surfaces should be designed with due consideration of the geometry.

(4) Transverse tensile stresses in adjacent elements should be considered. They may be due to concentrated compression according to Figure 10.3a, or to the expansion of soft padding according to Figure 10.3b. Reinforcement in case a) may be designed and located according to 6.5. Reinforcement in case b) should be placed close to the surfaces of the adjacent elements.

(5) In the absence of more accurate models, reinforcement in case b) may be calculated in accordance with Expression (10.5):

$$A_s = 0,25 \ (t \ / \ h) \ F_{Ed} \ / \ f_{yd} \qquad (10.5)$$

where:
A_s is the reinforcement area in each surface
t is the thickness of padding
h is the dimension of padding in direction of reinforcement
F_{Ed} is the compressive force in connection.

(6) The maximum capacity of compression connections can be determined according to 6.7, or can be based on analysis, possibly assisted by testing (for design assisted testing, see EN 1990).
a) Concentrated bearing   **b) Expansion of soft padding**

Figure 10.3: Transverse tensile stresses at compression connections.

10.9.4.4 Connections transmitting shear forces

(1) For shear transfer in interfaces between two concretes, e.g. a precast element and in situ concrete, see 6.2.5.

10.9.4.5 Connections transmitting bending moments or tensile forces

(1)P Reinforcement shall be continuous across the connection and anchored in the adjacent elements.

(2) Continuity may be obtained by, for example
  - lapping of bars
  - grouting of reinforcement into holes
  - overlapping reinforcement loops
  - welding of bars or steel plates
  - prestressing
  - mechanical devices (threaded or filled sleeves)
  - swaged connectors (compressed sleeves)

10.9.4.6 Half joints

(1) Half joints may be designed using strut-and-tie models according to 6.5. Two alternative models and reinforcements are indicated in Figure 10.4. The two models may be combined.

Note: The figure shows only the main features of strut-and-tie models.
Figure 10.4: Indicative models for reinforcement in half joints.

10.9.4.7 Anchorage of reinforcement at supports

(1) Reinforcement in supporting and supported members should be detailed to ensure anchorage in the respective node, allowing for deviations. An example is shown in Figure 10.5.

The effective bearing length a_1 is controlled by a distance d (see Figure 10.5) from the edge of the respective elements where:

$d_i = c_i + \Delta a_i$ with horizontal loops or otherwise end anchored bars
$d_i = c_i + \Delta a_i + r_i$ with vertically bent bars

Where
  c_i is concrete cover
  Δa_i is a deviation (see 10.9.5.2 (1)
  r_i is the bend radius

See Figure 10.5 and 10.9.5.2 (1) for definitions of Δa_2 or Δa_3.
Figure 10.5: Example of detailing of reinforcement in support

10.9.5 Bearings

10.9.5.1 General

(1)P The proper functioning of bearings shall be ensured by reinforcement in adjacent members, limitation of bearing stress and measures to account for movement or restraint.

(2)P For bearings which do not permit sliding or rotation without significant restraint, actions due to creep, shrinkage, temperature, misalignment, lack of plumb etc. shall be taken into account in the design of adjacent members.

(3) The effects of (2)P may require transverse reinforcement in supporting and supported members, and/or continuity reinforcement for tying elements together. They may also influence the design of main reinforcement in such members.

(4)P Bearings shall be designed and detailed to ensure correct positioning, taking into account production and assembling deviations.

(5)P Possible effects of prestressing anchorages and their recesses shall be taken into account.

10.9.5.2 Bearings for connected (non-isolated) members

(1) The nominal length a of a simple bearing as shown in Figure 10.6 may be calculated as:

$$a = a_1 + a_2 + a_3 + \sqrt{\Delta a_2^2 + \Delta a_3^2} \qquad (10.6)$$

where:
- a_1 is the net bearing length with regard to bearing stress, $a_1 = F_{Ed} / (b_1 f_{Rd})$, but not less than minimum values in Table 10.2
- F_{Ed} is the design value of support reaction
- b_1 is the net bearing width, see (3)
- f_{Rd} is the design value of bearing strength, see (2)
- a_2 is the distance assumed ineffective beyond outer end of supporting member, see Figure 10.6 and Table 10.3
- a_3 is the similar distance for supported member, see Figure 10.6 and Table 10.4
Figure 10.6: Example of bearing with definitions.

Δa_2 is an allowance for deviations for the distance between supporting members, see Table 10.5

Δa_3 is an allowance for deviations for the length of the supported member, $\Delta a_3 = l_n/2500$, l_n is length of member.

Table 10.2: Minimum value of a_1 in mm

Relative bearing stress, σ_{Ed}/f_{cd}	$\leq 0,15$	0,15 - 0,4	> 0,4
Line supports (floors, roofs)	25	30	40
Ribbed floors and purlins	55	70	80
Concentrated supports (beams)	90	110	140

Table 10.3: Distance a_2 (mm) assumed ineffective from outer end of supporting member. Concrete padstone should be used in cases (-)

Support material and type	σ_{Ed}/f_{cd}	$\leq 0,15$	0,15 - 0,4	> 0,4
Steel	line	0	0	10
	concentrated	5	10	15
Reinforced	line	5	10	15
concrete $\geq$ C30	concentrated	10	15	25
Plain concrete and	line	10	15	25
rein. concrete < C30	concentrated	20	25	35
Brickwork	line	10	15	(-)
	concentrated	20	25	(-)

Table 10.4: Distance a_3 (mm) assumed ineffective beyond outer end of supported member

Detailing of reinforcement	Support	
	Line	Concentrated
Continuous bars over support (restrained or not)	0	0
Straight bars, horizontal loops, close to end of member	5	15, but not less than end cover
Tendons or straight bars exposed at end of member	5	15
Vertical loop reinforcement	15	end cover + inner radius of bending

Table 10.5: Allowance Δa_2 for deviations for the clear distance between the faces of the supports. l = span length

Support material	Δa_2
Steel or precast concrete	$10 \leq l/1200 \leq 30$ mm
Brickwork or cast in-situ concrete	$15 \leq l/1200 + 5 \leq 40$ mm

(2) In the absence of other specifications, the following values can be used for the bearing strength:

$f_{Rd} = 0,4\ f_{cd}$　　　　　　for dry connections (see 10.9.4.3 (3) for definition)

$f_{Rd} = f_{bed} \le 0,85\ f_{cd}$　　　for all other cases

　　where
　　f_{cd}　　is the the lower of the design strengths for supported and supporting member
　　f_{bed}　　is the design strength of bedding material

(3) If measures are taken to obtain a uniform distribution of the bearing pressure, e.g. with mortar, neoprene or similar pads, the design bearing width b_1 may be taken as the actual width of the bearing. Otherwise, and in the absence of a more accurate analysis, b_1 should not be greater than to 600 mm.

10.9.5.3 Bearings for isolated members

(1)P The nominal length shall be 20 mm greater than for non-isolated members.

(2)P If the bearing allows movements in the support, the net bearing length shall be increased to cover possible movements.

(3)P If a member is tied other than at the level of its bearing, the net bearing length a_1 shall be increased to cover the effect of possible rotation around the tie.

10.9.6 Pocket foundations

10.9.6.1 General

(1)P Concrete pockets shall be capable of transferring vertical actions, bending moments and horizontal shears from columns to the soil. The pocket shall be large enough to enable a good concrete filling below and around the column.

10.9.6.2 Pockets with keyed surfaces

(1) Pockets expressly wrought with indentations or keys may be considered to act monolithically with the column.

(2)   Where vertical tension due to moment transfer occurs careful detailing of the overlap reinforcement of the similarly wrought column and the foundation is needed, allowing for the separation of the lapped bars. The lap length according to 8.6 should be increased by at least the horizontal distance between bars in the column and in the foundation (see Figure 10.7 (a)) Adequate horizontal reinforcement for the lapped splice should be provided.

(3)   The punching shear design should be as for monolithic column/foundation connections according to 6.4, as shown in Figure 10.7 (a), provided the shear transfer between the column and footing is verified. Otherwise the punching shear design should be as for pockets with smooth surfaces.

10.9.6.3 Pockets with smooth surfaces

(1) The forces and the moment may be assumed to be transferred from column to foundation by compressive forces F_1, F_2 and F_3 through the concrete filling and corresponding friction forces, as shown in Figure 10.7 (b). This model requires $l \geq 1,2 \; h$.

(a) with keyed joint surface   (b) with smooth joint surface
Figure 10.7: Pocket Foundations

(2) The coefficient of friction should not be taken greater than $\mu = 0,3$.

(3) Special attention should be paid to:
 - detailing of reinforcement for F_1 in top of pocket walls
 - transfer of F_1 along the lateral walls to the footing
 - anchorage of main reinforcement in the column and pocket walls
 - shear resistance of column within the pocket
 - punching resistance of the footing slab under the column force, the calculation for which may take into account the insitu structural concrete placed under the precast element.

10.9.7 Tying systems

(1)   For plate elements loaded in their own plane, e.g. in walls and floor diaphragms, the necessary interaction may be obtained by tying the structure together with peripheral and/or internal ties.

The same ties may also act to prevent progressive collapse according to 9.10.

SECTION 11   LIGHTWEIGHT AGGREGATE CONCRETE STRUCTURES

11.1   General

(1)P This section provides additional requirements for lightweight aggregate concrete (LWAC). Reference is made to the other Sections (1 to 10 and 12) of this document and the Annexes.

> **Note.**   Headings are numbered 11 followed by the number of the corresponding main section. Headings of lower level are numbered consecutively, without connection to sub-headings in previous sections. If alternatives are given for Expressions, Figures or Tables in the other sections, the original reference numbers are also prefixed by 11.

11.1.1 Scope

(1)P All clauses of the Sections 1 to 10 and 12 are generally applicable, unless they are substituted by special clauses given in this section. In general, where strength values originating from Table 3.1 are used in Expressions, those values have to be replaced by the corresponding values for lightweight concrete, given in this section in Table 11.3.1.

 (2)P Section 11 applies to all concretes with closed structure made with natural or artificial mineral lightweight aggregates, unless reliable experience indicates that provisions different from those given can be adopted safely.

(3) This section does not apply to aerated concrete either autoclaved or normally cured nor lightweight aggregate concrete with an open structure.

(4)P Lightweight aggregate concrete is concrete having a closed structure and a density of not more than 2200 kg/m^3 consisting of or containing a proportion of artificial or natural lightweight aggregates having a particle density of less than 2000 kg/m^3

11.1.2 Special symbols

1(P) The following symbols are used specially for lightweight concrete:

LC   the strength classes of lightweight aggregate concrete are preceded by the symbol LC
η_E is a conversion factor for calculating the modulus of elasticity
η_1 is a coefficient for determining tensile strength
η_2 is a coefficient for determining creep coefficient
η_3 is a coefficient for determining drying shrinkage
ρ is the oven-dry density of lightweight aggregate concrete in kg/m^3

For the mechanical properties an additional subscript l (lightweight) is used.

11.2   Basis of design

1(P) Section 2 is valid for lightweight concrete without modifications.

11.3   Materials

11.3.1   Concrete

(1)P In EN 206-1 lightweight aggregate is classified according to its density as shown in Table 11.1. In addition this table gives corresponding densities for plain and reinforced concrete with normal percentages of reinforcement which may be used for design purposes in calculating self-weight or imposed permanent loading. Alternatively, the density may be specified as a target value.

(2) Alternatively the contribution of the reinforcement to the density may be determined by calculation.

Table 11.1:   Density classes and corresponding design densities of LWAC according to EN 206-1

Density class		1,0	1,2	1,4	1,6	1,8	2,0
Density (kg/m^3)		801–1000	1001–1200	1201–1400	1401–1600	1601–1800	1801–2000
Density (kg/m^3)	Plain concrete	1050	1250	1450	1650	1850	2050
	Reinforced concrete	1150	1350	1550	1750	1950	2150

(3) The tensile strength of lightweight aggregate concrete may be obtained by multiplying the f_{ct} values given in Table 3.1 by a coefficient:

$$\eta_1 = 0{,}40 + 0{,}60\rho/2200 \tag{11.1}$$

where
   ρ is the upper limit of the density for the relevant class in accordance with Table 11.1

11.3.2   Elastic deformation

(1) An estimate of the mean values of the secant modulus E_{lcm} for LWAC may be obtained by multiplying the values in Table 3.1, for normal density concrete, by the following coefficient:

$$\eta_E = (\rho/2200)^2 \tag{11.2}$$

where ρ denotes the oven-dry density in accordance with EN 206-1 Section 4 (see Table 11.1).

Where accurate data are needed, e.g. where deflections are of great importance, tests should be carried out in order to determine the E_{lcm} values in accordance with ISO 6784.

   Note: A Country's National Annex may refer to non-contradictory complementary information.

(2) The coefficient of thermal expansion of LWAC depends mainly on the type of aggregate used and varies over a wide range between about $4 \cdot 10^{-6}$ and $14 \cdot 10^{-6}$/K

For design purposes where thermal expansion is of no great importance, the coefficient of thermal expansion may be taken as $8 \cdot 10^{-6}$/K.

The differences between the coefficients of thermal expansion of steel and lightweight aggregate concrete need not be considered in design.

Table 11.3.1: Stress and deformation characteristics for lightweight concrete

	Strength classes for light weight concrete													Analytical relation/Explanation
f_{lck} (MPa)	12	16	20	25	30	35	40	45	50	55	60	70	80	
$f_{lck,cube}$ (MPa)	13	18	22	28	33	38	44	50	55	60	66	77	88	
f_{lcm} (MPa)	17	22	28	33	38	43	48	53	58	63	68	78	88	For $f_{lck} \geq 20$ MPa $f_{lcm} = f_{lck} + 8$ (MPa)
f_{lctm} (MPa)	$f_{lctm} = f_{ctm} \cdot \eta_1$													$\eta_1 = 0{,}40 + 0{,}60\rho/2200$
$f_{lctk,0,05}$ (MPa)	$f_{lctk,0,05} = f_{ctk,0,05} \cdot \eta_1$													5% - fractile
$f_{lctk,0,95}$ (MPa)	$f_{lctk,0,95} = f_{ctk,0,95} \cdot \eta_1$													95% - fractile
E_{lcm} (GPa)	$E_{lcm} = E_{cm} \cdot \eta_E$													$\eta_E = (\rho/2200)^2$
ε_{lc1} (‰)	$kf_{lcm}/(E_{lci} \cdot \eta_E)$ $\begin{cases} k = 1{,}1 \text{ for sanded lightweight aggregate concrete} \\ k = 1.0 \text{ for all lightweight aggregate concrete} \end{cases}$													see Figure 3.2
ε_{lcu1} (‰)	ε_{lc1}													see Figure 3.2
ε_{lc2} (‰)	2,0									2,2	2,3	2,4	2,5	see Figure 3.3
ε_{lcu2} (‰)	3,5 η_1									3,1η_1	2,9η_1	2,7η_1	2,6η_1	see Figure 3.3 $|\varepsilon_{lcu2u}| \geq |\varepsilon_{lc2}|$
n	2,0									1,75	1,6	1,45	1,4	
ε_{lc3} (‰)	1,75									1,8	1,9	2,0	2,2	see Figure 3.4
ε_{lcu3} (‰)	3,5 η_1									3,1η_1	2,9η_1	2,7η_1	2,6η_1	see Figure 3.4 $|\varepsilon_{lcu3}| \geq |\varepsilon_{lc3}|$

11.3.3 Creep and shrinkage

(1) For lightweight aggregate concrete the creep coefficient φ may be assumed equal to the value of normal density concrete multiplied by a factor $(\rho/2200)^2$.

The creep strains so derived should be multiplied by a factor, η_2, given by

$\eta_2 = 1,3$ for $f_{lck} \leq LC16/18$
$\quad = 1,0$ for $f_{lck} \geq LC20/22$

(2) The final drying shrinkage values for lightweight concrete can be obtained by multiplying the values for normal density concrete in Table 3.2 by a factor, η_3, given by

$\eta_3 = 1,5$ for $f_{lck} \leq LC16/18$
$\quad = 1,2$ for $f_{lck} \geq LC20/22$

(3) The Expressions (3.11), (3.12) and (3.13), which provide information for autogenous shrinkage, give maximum values for lightweight aggregate concretes, where no supply of water from the aggregate to the drying microstructure is possible. If water-saturated, or even partially saturated lightweight aggregate is used, the autogenous shrinkage values will be considerably reduced.

11.3.4 Stress-strain relations for non-linear structural analysis

(1) For lightweight aggregate concrete the values ε_{c1} and ε_{cu1} given in Figure 3.2 should be substituted by ε_{lc1} and ε_{lcu1} given in Table 11.3.1.

11.3.5 Design compressive and tensile strengths

(1)P The value of the design compressive strength is defined as

$$f_{lcd} = \alpha_{lcc} \, f_{lck} / \gamma_c \qquad\qquad (11.3.15)$$

where γ_c is the partial safety factor for concrete, see 2.4.1.4, and α_{lcc} is a coefficient according to 3.1.6 (1)P.

Note: The value of α_{lcc} for use in a Country may be found in its National Annex. The recommended value is 0,85.

(2)P The value of the design tensile strength is defined as

$$f_{lctd} = \alpha_{lct} \, f_{lctk} / \gamma_c \qquad\qquad (11.3.16)$$

where γ_c is the partial safety factor for concrete, see 2.4.1.4 and α_{lct} is a coefficient according to 3.1.6 (2)P.

Note: The value of α_{lct} for use in a Country may be found in its National Annex. The recommended value is 0,85.

11.3.6 Stress-strain relations for the design of sections

(1) For lightweight aggregate concrete the values ε_{c2} and ε_{cu2} given in Figure 3.3 should be replaced with the values of ε_{lc2} and ε_{lcu2} given in Table 11.3.1.

(2) For lightweight aggregate concrete the values ε_{c3} and ε_{cu3} given in Figure 3.4 should be replaced with the values of ε_{lc3} and ε_{lcu3} given in Table 11.3.1.

11.3.7 Confined concrete

(1) If more precise data are not available, the stress-strain relation shown in Figure 3.6 may be used, with increased characteristic strength and strains according to:

$$f_{lck,c} = f_{lck} (1,0 + k\sigma_2/f_{lck}) \tag{11.3.24}$$

Note: The value of k for use in a Country may be found in its National Annex. The recommended value is:
    1,1 for lightweight aggregate concrete with sand as the fine aggregate
    1,0 for lightweight aggregate (both fine and coarse aggregate) concrete

$$\varepsilon_{lc2,c} = \varepsilon_{lc2} (f_{lckc}/f_{lck})^2 \tag{11.3.26}$$
$$\varepsilon_{lcu2,c} = \varepsilon_{lcu2} + 0,2\sigma_2/f_{lck} \tag{11.3.27}$$

where ε_{lc2} and ε_{lcu2} follow from Table 11.3.1.

11.4 Durability and cover to reinforcement

11.4.1 Environmental conditions

(1) For lightweight aggregate concrete in Table 4.1 the same indicative exposure classes can be used as for normal density concrete.

11.4.2 Concrete cover and properties of concrete

(1)P For lightweight aggregate concrete the values of minimum concrete cover given in Table 4.2 shall be increased by 5 mm.

11.5 Structural analysis

11.5.1 Rotational capacity

Note: For light weight concrete the value of θ_{plast}, as shown in Figure 5.6N, should be multiplied by a factor $\varepsilon_{lc2u}/\varepsilon_{c2u}$.

11.6 Ultimate limit states

11.6.1 Members not requiring design shear reinforcement

(1) The design value of the shear resistance of a lightweight concrete member without shear reinforcement $V_{lRd,c}$ follows from:

$$V_{lRd,c} = [C_{lRd,c}\eta_1 k(100\rho_l f_{lck})^{1/3} + k_1\sigma_{cp}] b_w d \geq (v_{l,min} + k_1\sigma_{cp})b_w d \tag{11.6.2}$$

where η_1 is defined in Expression (11.1), f_{lck} is taken from Table 11.3.1 and σ_{cp} is the mean compressive stress in the section due to axial force and prestress.

Note: The values of $C_{lRd,c}$, $v_{l,min}$ and k_1 for use in a Country may be found in its National Annex. The recommended value for $C_{lRd,c}$ is $0,15/\gamma_c$, for $v_{l,min}$ is $0,30\ k^{3/2}f_{lck}^{1/2}$ and that k_1 is 0,15.

Table 11.6.1N: Values of $v_{l,min}$ for given values of d and f_{ck}

d (mm)	$v_{l,min}$ (MPa)						
	f_{ck} (MPa)						
	20	30	40	50	60	70	80
200	0.36	0.44	0.50	0.56	0.61	0.65	0.70
400	0.29	0.35	0.39	0.44	0.48	0.52	0.55
600	0.25	0.31	0.35	0.39	0.42	0.46	0.49
800	0.40	0.28	0.32	0.36	0.39	0.42	0.45
≥ 1000	0.22	0.27	0.31	0.34	0.37	0.40	0.43

(2) The shear force, V_{Ed}, calculated without reduction β (see 6.2.2 (6)) should always satisfy the condition:

$$V_{Ed} \leq 0,5 \, \eta_1 \, b_w \, d\nu_l \, f_{lcd} \tag{11.6.5}$$

where

η_1 is in accordance with 11.6.1 (1)

ν_l is in accordance with 11.6.2 (1)

11.6.2 Members requiring design shear reinforcement

(1) The reduction factor for the crushing resistance of the concrete struts is ν_1.

Note: The value of ν_1 for use in a Country may be found in its National Annex. The recommended value follows from:

$$\nu_1 = 0,5 \, \eta_1 \, (1 - f_{lck}/250) \tag{11.6.6N}$$

11.6.3 Torsion

11.6.3.1 Design procedure

(1) In Expression (6.30) for lightweight concrete ν is taken equal to ν_1 according to 11.6.2 (1).

11.6.4 Punching

11.6.4.1 Punching shear resistance of slabs or column bases without shear reinforcement

(1) The punching shear resistance per unit area of a lightweight concrete slab follows from

$$v_{lRd,c} = C_{lRd,c} \, k \, \eta_1 (100\rho_l \, f_{lck})^{1/3} + k_2 \, \sigma_{cp} \geq (\eta_1 v_{l,min} + k_2 \sigma_{cp}) \tag{11.6.47}$$

where

η_1 is defined in Expression (11.1)

$C_{lRd,c}$ see 11.6.1 (1)

$v_{l,min}$ see 11.6.1 (1)

Note: The value k_2 for use in a Country may be found in its National Annex. The recommended value is 0,08

(2) The punching shear resistance, V_{lRd}, of lightweight concrete column bases follows from

$$v_{lRd,c} = C_{lRd,c}\ \eta_1 k\ (100\rho_l\ f_{lck})^{1/3}\ 2d/a\ \ \geq \eta_1\ v_{lmin}{\cdot}2d/a \tag{11.6.50}$$

where
    η_1 is defined in Expression (11.1)
    $\rho_1 \geq 0{,}005$
    $C_{lRd,c}$ see 11.6.1 (1)
    $v_{l,min}$ see 11.6.1 (1)

11.6.4.2 Punching shear resistance of slabs or column bases with shear reinforcement

(1) Where shear reinforcement is required the punching shear resistance is given by

$$v_{lRd,cs} = 0{,}75 v_{lRd,c} + 1{,}5 \left(\frac{d}{s_r} \right) \left(\frac{1}{u_1 d} \right) A_{sw} f_{ywd,eff}\ \sin\alpha \tag{11.6.52}$$

where $v_{lRd,c}$ is defined in Expression (11.6.47) or (11.6.50) whichever is relevant.

(2) Adjacent to the column the punching shear capacity is limited to a maximum of

$$v_{Ed} = \frac{V_{Ed}}{u_0 d} \leq v_{lRd,max} = 0{,}5\, \nu\, f_{lcd} \tag{11.6.53}$$

where ν is taken equal to ν_1 defined in 11.6.2 (1).

11.6.5 Partially loaded areas

(1) For a uniform distribution of load on an area A_{c0} (see Figure 6.29) the concentrated resistance force may be determined as follows:

$$F_{Rdu} = A_{c0} \cdot f_{lcd} \cdot \left[A_{c1}/A_{c0} \right]^{\frac{\rho}{4400}} \leq 3{,}0 \cdot f_{lcd} \cdot A_{c0} \left(\frac{\rho}{2200} \right) \tag{11.6.63}$$

11.6.6 Fatigue

(1) For fatigue verification of elements made with lightweight aggregated concrete special consideration is required. Reference should be made to a European Technical Approval.

11.7 Serviceability limit states

(1)P The basic ratios of span/effective depth for reinforced concrete members without axial compression, given in 7.4.2, should be reduced by a factor $\eta_E^{0,15}$ when applied to LWAC.

11.8 Detailing of reinforcement - General

11.8.1 Permissible mandrel diameters for bent bars

(1) For lightweight aggregate concrete the mandrel sizes for normal density concrete given in 8.4.4 to avoid splitting of the concrete at bends, hoops and loops, should be increased by 50%.

11.8.2 Ultimate bond stress

(1) The design value of the ultimate bond stress for bars in lightweight concrete may be calculated using Expression 8.2, by substituting the value f_{lctd} for f_{ctd}, with $f_{lctd} = f_{lctk,0,05}/\gamma_c$. The values for $f_{lctk,0,05}$ are found in Table 11.3.1.

11.9 Detailing of members and particular rules

(1) The diameter of bars embedded in LWAC should not normally exceed 32 mm. For LWAC bundles of bars should not consist of more than two bars and the equivalent diameter should not exceed 45 mm.

11.10 Additional rules for precast concrete elements and structures

(1) Section 10 may be applied to lightweight aggregate concrete without modifications.

11.12 Plain and lightly reinforced concrete structures

(1) Section 12 may be applied to lightweight aggregate concrete without modifications.

SECTION 12 PLAIN AND LIGHTLY REINFORCED CONCRETE STRUCTURES

12.1 General

(1)P This section provides additional rules for plain concrete structures or where the reinforcement provided is less than the minimum required for reinforced concrete.

> **Note:** Headings are numbered 12 followed by the number of the corresponding main section. Headings of lower level are numbered consecutively, without reference to subheadings in previous sections.

(2) This section applies to members, for which the effect of dynamic actions may be ignored. It does not apply to the effects such as those from rotating machines and traffic loads. Examples of such members include:
- members mainly subjected to compression other than that due to prestressing, e.g. walls, columns, arches, vaults, and tunnels;
- strip and pad footings for foundations;
- retaining walls;
- piles whose diameter is ≥ 600 mm and where $N_{Ed}/A_c \leq 0,3f_{ck}$.

(3) Where members are made with lightweight aggregate concrete with closed structure according to Section 11 or for precast concrete elements and structures covered by this Eurocode, the design rules should be modified accordingly.

(4) Members using plain concrete do not preclude the provision of steel reinforcement needed to satisfy serviceability and/or durability requirements, nor reinforcement in certain parts of the members. This reinforcement may be taken into account for the verification of local ultimate limit states as well as for the checks of the serviceability limit states.

12.3 Materials

12.3.1 Concrete: additional design assumptions

(1) Due to the less ductile properties of plain concrete the values for $\alpha_{cc,pl}$ and $\alpha_{ct,pl}$ should be taken to be less than α_{cc} and α_{ct} for reinforced concrete.

> **Note:** The values of $\alpha_{cc,pl}$ and $\alpha_{ct,pl}$ for use in a Country may be found in its National Annex. The recommended value for both is 0,8.

(2) When tensile stresses are considered for the design resistance of plain concrete members, the stress strain diagram (see 3.1.7) may be extended up to the tensile design strength using Expression (3.16) or a linear relationship.

$$f_{ctd} = \alpha_{ct}\, f_{ctk,0,05}/\gamma_c \qquad\qquad (12.1)$$

(3) Fracture mechanic methods may be used provided it can be shown that they lead to the required level of safety.

12.5 Structural analysis: ultimate limit states

(1) Since plain concrete members have limited ductility, linear analysis with redistribution or a plastic approach to analysis, e.g. methods without an explicit check of the deformation capacity, should not be used unless their application can be justified.

(2) Structural analysis may be based on the non-linear or the linear elastic theory. In the case of a non-linear analysis (e.g. fracture mechanics) a check of the deformation capacity should be carried out.

12.6 Ultimate limit states

12.6.1 Design resistance to bending and axial force

(1) In the case of walls, subject to the provision of adequate construction details and curing, the imposed deformations due to temperature or shrinkage may be ignored.

(2) The stress-strain relations for plain concrete should be taken from 3.1.7.

(3) The axial resistance, N_{Rd}, of a rectangular cross-section with a uniaxial eccentricity, e, in the direction of h_w, may be taken as:

$$N_{Rd} = \eta f_{cd} \times b \times h_w \times (1\text{-}2e/h_w) \tag{12.2}$$

where:
$\quad \eta f_{cd} \quad$ is the design effective compressive strength (see 3.1.7 (3)
$\quad b \quad\quad$ is the overall width of the cross-section (see Figure 12.1)
$\quad h_w \quad$ is the overall depth of the cross-section
$\quad e \quad\quad$ is the eccentricity of N_{Ed} in the direction h_w.

Note: Where other simplified methods are used they should not be less conservative than a rigorous method using a stress-strain relationship given in 3.1.7.

Figure 12.1: Notation for plain walls

12.6.2 Local failure

(1)P   Unless measures to avoid local tensile failure of the cross-section have been taken, the maximum eccentricity of the axial force N_{Ed} in a cross-section shall be limited to avoid large cracks.

12.6.3 Shear

(1) In plain concrete members account may be taken of the concrete tensile strength in the ultimate limit state for shear, provided that either by calculations or by experience brittle failure can be excluded and adequate resistance can be ensured.

(2) For a section subject to a shear force V_{Ed} and a normal force N_{Ed} acting over a compressive area A_{cc} the absolute value of the components of design stress should be taken as:

$$\sigma_{cp} = N_{Ed} / A_{cc} \qquad\qquad\qquad (12.3)$$

$$\tau_{cp} = k V_{Ed} / A_{cc} \qquad\qquad\qquad (12.4)$$

Note: the value of k for use in a Country may be found in its National Annex. The recommended value is 1,5.

and the following should be checked:

$$\tau_{cp} \leq f_{cvd}$$

where:

if $\sigma_{cp} \leq \sigma_{c,lim}$ $\qquad\qquad f_{cvd} = \sqrt{f_{ctd}^2 + \sigma_{cp} f_{ctd}}$ $\qquad\qquad (12.5)$

or

if $\sigma_{cp} > \sigma_{c,lim}$ $\qquad\qquad f_{cvd} = \sqrt{f_{ctd}^2 + \sigma_{cp} f_{ctd} - \left(\dfrac{\sigma_{cp} - \sigma_{c,lim}}{2}\right)^2}$ $\qquad (12.6)$

$$\sigma_{c,lim} = f_{cd} - 2\sqrt{f_{ctd}\left(f_{ctd} + f_{cd}\right)} \qquad\qquad (12.7)$$

where:
   f_{cvd} is the concrete design strength in shear and compression
   f_{cd} is the concrete design strength in compression
   f_{ctd} is concrete design strength in tension

(3)   A concrete member may be considered to be uncracked in the ultimate limit state if either it remains completely under compression or if the absolute value of the principal concrete tensile stress σ_{ct1} does not exceed f_{ctd}.

12.6.4 Torsion

(1) Cracked members should not normally be designed to resist torsional moments unless it can be justified otherwise.

12.6.5 Ultimate limit states induced by structural deformation (buckling)

12.6.5.1 Slenderness of columns and walls

(1) The slenderness of a column or wall is given by
$$\lambda = l_0/i \qquad\qquad\qquad (12.8)$$

where:
 i is the minimum radius of gyration
   l_0 is the effective length of the member which can be assumed to be:

$$l_0 = \beta \cdot l_w \qquad\qquad\qquad (12.9)$$

where:
l_w clear height of the member
β coefficient which depends on the support conditions:
for columns $\beta = 1$ should in general be assumed;
for cantilever columns or walls $\beta = 2$;
for other walls β-values are given in Table 12.1.

Table 12.1: Values of β for different edge conditions

Lateral restraint	Sketch	Expression	Factor β	
along two edges			$\beta = 1,0$ for any ratio of l_w/b	
Along three edges		$\beta = \dfrac{1}{1+\left(\dfrac{l_w}{3b}\right)^2}$	b/l_w / 0,2 / 0,4 / 0,6 / 0,8 / 1,0 / 1,5 / 2,0 / 5,0	β / 0,26 / 0,59 / 0,76 / 0,85 / 0,90 / 0,95 / 0,97 / 1,00
Along four edges		If $b \geq l_w$ $\beta = \dfrac{1}{1+\left(\dfrac{l_w}{b}\right)^2}$ If $b < l_w$ $\beta = \dfrac{b}{2l_w}$	b/l_w / 0,2 / 0,4 / 0,6 / 0,8 / 1,0 / 1,5 / 2,0 / 5,0	β / 0,10 / 0,20 / 0,30 / 0,40 / 0,50 / 0,69 / 0,80 / 0,96

Ⓐ - Floor slab   Ⓑ - Free edge   Ⓒ - Transverse wall

Note: The information in Table 12.1 assumes that the wall has no openings with a height exceeding 1/3 of the wall height l_w or with an area exceeding 1/10 of the wall area. In walls laterally restrained along 3 or 4 sides with openings exceeding these limits, the parts between the openings should be considered as laterally restrained along 2 sides only and be designed accordingly.

(2) The β-values should be increased appropriately if the transverse bearing capacity is affected by chases or recesses.

(3) A transverse wall may be considered as a bracing wall if:
- its total depth is not less than 0,5 h_w, where h_w is the overall depth of the braced wall;
- it has the same height l_w as the braced wall under consideration;
- its length l_{ht} is at least equal to l_w / 5, where l_w denotes the clear height of the braced wall;

- within the length l_{ht} the transverse wall has no openings.

(4) In the case of a wall connected along the top and bottom in flexurally rigid manner by insitu concrete and reinforcement, so that the edge moments can be fully resisted, the values for β given in Table 12.1 may be factored by 0,85.

(5) The slenderness of walls in plain concrete cast insitu should generally not exceed $\lambda = 86$ (i.e. $l_0/h_w = 25$).

12.6.5.2 Simplified design method for walls and columns

(1)   In absence of a more rigorous approach, the design resistance in terms of axial force for a slender wall or column in plain concrete may be calculated as follows:

$$N_{Rd} = b \times h_w \times f_{cd} \times \Phi \qquad (12.10)$$

where
N_{Rd} is the axial resistance
b is the overall width of the cross-section
h_w is the overall depth of the cross-section
Φ Factor taking into account eccentricity, including second order effects and normal effects of creep; see below

For braced members, the factor Φ may be taken as:

$$\Phi = (1,14 \times (1\text{-}2e_{tot}/h_w) \text{ - } 0,02 \times l_0/h_w \leq (1\text{-}2\,e_{tot}/h_w) \qquad (12.11)$$

where:
$$e_{tot} = e_o + e_i \qquad (12.12)$$

e_o is the first order eccentricity including, where relevant, the effects of floors (e.g. possible clamping moments transmitted to the wall from a slab) and horizontal actions
e_i is the additional eccentricity covering the effects of geometrical imperfections, see 5.2

(2)   Other simplified methods may be used provided that they are not less conservative than a rigorous method in accordance with 5.8.

12.7   Serviceability limit states

(1) Stresses should be checked where structural restraint is expected to occur.

(2) The following measures to ensure adequate serviceability should be considered:

a) with regard to crack formation:
- limitation of concrete tensile stresses to acceptable values;
- provision of subsidiary structural reinforcement (surface reinforcement, tying system where necessary);
- provision of joints;
- choice of concrete technology (e.g. appropriate concrete composition, curing);
- choice of appropriate method of construction.

b) with regard to limitation of deformations:
- a minimum section size (see 12.9 below);

- limitation of slenderness in the case of compression members.

(3) Any reinforcement provided in plain concrete members, although not taken into account for load bearing purposes, should comply with 4.4.1.

12.9 Detailing of members and particular rules

12.9.1 Structural members

(1) The overall depth h_w of a wall should not be smaller than 120 mm for cast in-situ concrete walls.

(2) Where chases and recesses are included checks should be carried out to assure the adequate strength and stability of the member.

12.9.2 Construction joints

(1) Where tensile stresses in the concrete occur in construction joints are expected to occur, reinforcement should be detailed to control cracking.

12.9.3 Strip and pad footings

(1) In the absence of more detailed data, axially loaded strip and pad footings may be designed and constructed as plain concrete provided that:

$$\frac{0{,}85 \cdot h_F}{a} \geq \sqrt{(9\sigma_{gd}/f_{ctd})} \tag{12.13}$$

where:
h_F is the foundation depth
a is the projection from the column face (see Figure 12.2)
σ_{gd} is the design value of the ground pressure
f_{ctd} is the design value of the concrete tensile strength (in the same unit as σ_{gd})

As a simplification the relation $h_F/a \geq 2$ may be used.
Figure: 12.2: Unreinforced pad footings; notations

Annex A (informative)

Modification of partial factors for materials

A.1 General

(1) The partial factors for materials given in 2.4.2.4 correspond to geometrical deviations of Class 1 in ENV 13670-1 and normal level of workmanship and inspection (e.g. Inspection Class 2 in ENV 13670-1).

(2) Recommendations for reduced partial factors for materials are given in this Informative Annex. More detailed rules on control procedures may be given in product standards for precast elements.

> **Note:** For more information see Annex B of EN 1990.

A.2 In situ concrete structures

A.2.1 Reduction based on quality control and reduced deviations

(1) If execution is subjected to a quality control system, which ensures that unfavourable deviations of cross-section dimensions are within the reduced deviations given in Table A.1, the partial safety factor for reinforcement may be reduced to $\gamma_{s,red1}$.

Table A.1: Reduced deviations

| h or b (mm) | Reduced deviations (mm) | |
	Cross-section dimension $\pm\Delta h, \Delta b$ (mm)	Position of reinforcement $+\Delta c$ (mm)
≤ 150	5	5
400	10	10
≥ 2500	30	20
Note 1: Linear interpolation may be used for intermediate values.		
Note 2: $+\Delta c$ refers to the mean value of reinforcing bars or prestressing tendons in the cross-section or over a width of one metre (e.g. slabs and walls).		

> **Note:** The value of $\gamma_{s,red1}$ for use in a Country may be found in its National Annex. The recommended value is 1,1.

(2) Under the condition given in A.2.1 (1), and if the coefficient of variation of the concrete strength is shown not to exceed 10 %, the partial safety factor for concrete may be reduced to $\gamma_{c,red1}$.

> **Note:** The value of $\gamma_{c,red1}$ for use in a Country may be found in its National Annex. The recommended value is 1,4.

A.2.2 Reduction based on using reduced or measured geometrical data in design

(1) If the calculation of design resistance is based on critical geometrical data, including effective depth (see Figure A.1), which are either:
- reduced by deviations, or
- measured in the finished structure,

199

the partial safety factors may be reduced to $\gamma_{s,red2}$ and $\gamma_{c,red2}$.

> **Note:** The values of $\gamma_{s,red2}$ and $\gamma_{c,red2}$ for use in a Country may be found in its National Annex. The recommended value of $\gamma_{s,red2}$ is 1,05 and of $\gamma_{c,red2}$ is 1,45.

a) Cross section   **b) Position of reinforcement**
                              (unfavourable direction for effective depth)
Figure A.1: Cross-section deviations

(2) Under the conditions given in A.2.2 (1) and provided that the coefficient of variation of the concrete strength is shown not to exceed 10%, the partial factor for concrete may be reduced to $\gamma_{c,red3}$.

> **Note:** The value of $\gamma_{c,red3}$ for use in a Country may be found in its National Annex. The recommended value is 1,35.

A.2.3 Reduction based on assessment of concrete strength in finished structure

(1) For concrete strength values based on testing in a finished structure or element, see EN 13791[1], EN 206-1 and relevant product standards, γ_c may be reduced by the conversion factor η.

> **Note:** The value of η for use in a Country may be found in its National Annex. The recommended value is 0,85.

The value of γ_c to which this reduction is applied may already be reduced according to A.2.1 or A.2.2. However, the resulting value of the partial factor should not be taken less than $\gamma_{c,red4}$.

> **Note:** The value of $\gamma_{c,red4}$ for use in a Country may be found in its National Annex. The recommended value is 1,3.

A.3   Precast products

A.3.1 General

(1) These provisions apply to precast products as described in Section 10, linked to quality assurance systems and given attestation of conformity.

> **Note:** Factory production control of CE-marked precast products is certified by notified body (Attestation level 2+).

---

[1] *EN 13791. Assessment of concrete compressive strength in structures or in structural elements*

A.3.2 Partial factors for materials

(1) Reduced partial factors for materials, $\gamma_{c,pcred}$ and $\gamma_{s,pcred}$ may be used in accordance with the rules in A.2, if justified by adequate control procedures.

(2) Recommendations for factory production control required to allow the use of reduced partial factors for materials are given in product standards. General recommendations are given in EN 13369.

A.4   Precast elements

(1) The rules given in A.2 for insitu concrete structures also apply to precast concrete elements as defined in 10.1.1.

ANNEX B (Informative)

Creep and shrinkage strain

B.1 Basic equations for determining the creep coefficient

(1) The creep coefficient $\varphi(t,t_0)$ may be calculated from:

$$\varphi\,(t,t_0) = \varphi_0 \cdot \beta_c(t,t_0) \tag{B.1}$$

where:

φ_0 is the notional creep coefficient and may be estimated from:

$$\varphi_0 = \varphi_{RH} \cdot \beta(f_{cm}) \cdot \beta(t_0) \tag{B.2}$$

φ_{RH} is a factor to allow for the effect of relative humidity on the notional creep coefficient:

$$\varphi_{RH} = 1 + \frac{1 - RH/100}{0,1 \cdot \sqrt[3]{h_0}} \qquad \text{for } f_{cm} \le 35 \text{ MPa} \tag{B.3a}$$

$$\varphi_{RH} = \left[1 + \frac{1 - RH/100}{0,1 \cdot \sqrt[3]{h_0}} \cdot \alpha_1 \right] \cdot \alpha_2 \quad \text{for } f_{cm} > 35 \text{ MPa} \tag{B.3b}$$

RH is the relative humidity of the ambient environment in %

$\beta\,(f_{cm})$ is a factor to allow for the effect of concrete strength on the notional creep coefficient:

$$\beta(f_{cm}) = \frac{16,8}{\sqrt{f_{cm}}} \tag{B.4}$$

f_{cm} is the mean compressive strength of concrete in MPa at the age of 28 days
$\beta\,(t_0)$ is a factor to allow for the effect of concrete age at loading on the notional creep coefficient:

$$\beta(t_0) = \frac{1}{(0,1 + t_0^{0,20})} \tag{B.5}$$

h_0 is the notional size of the member in mm where:

$$h_0 = \frac{2A_c}{u} \tag{B.6}$$

A_c is the cross-sectional area
u is the perimeter of the member in contact with the atmosphere
$\beta_c(t,t_0)$ is a coefficient to describe the development of creep with time after loading, and may be estimated using the following Expression:

$$\beta_c\left(t,t_0\right) = \left[\frac{\left(t-t_0\right)}{\left(\beta_H + t - t_0\right)}\right]^{0,3}$$

(B.7)

t is the age of concrete in days at the moment considered
t_0 is the age of concrete at loading in days
$t - t_0$ is the non-adjusted duration of loading in days
β_H is a coefficient depending on the relative humidity (RH in %) and the notional member size (h_0 in mm). It may be estimated from:

$\beta_H = 1,5\,[1 + (0,012\,RH)^{18}]\,h_0 + 250 \le 1500$ for $f_{cm} \le 35$ (B.8a)

$\beta_H = 1,5\,[1 + (0,012\,RH)^{18}]\,h_0 + 250\,\alpha_3 \le 1500\,\alpha_3$ for $f_{cm} \ge 35$ (B.8b)

$\alpha_{1/2/3}$ are coefficients to consider the influence of the concrete strength:

$$\alpha_1 = \left[\frac{35}{f_{cm}}\right]^{0,7} \qquad \alpha_2 = \left[\frac{35}{f_{cm}}\right]^{0,2} \qquad \alpha_3 = \left[\frac{35}{f_{cm}}\right]^{0,5}$$

(B.8c)

(2) The effect of type of cement (see 3.1.2 (6)) on the creep coefficient of concrete may be taken into account by modifying the age of loading t_0 in Expression (B.5) according to the following Expression:

$$t_0 = t_{0,T} \cdot \left(\frac{9}{2 + t_{0,T}^{1,2}} + 1\right)^{\alpha} \ge 0,5$$

(B.9)

where:
    $t_{0,T}$ is the temperature adjusted age of concrete at loading in days adjusted according to Expression (B.10)
    α is a power which depends on type of cement
        = -1 for cement Class S
        = 0 for cement Class N
        = 1 for cement Class R

(3) The effect of elevated or reduced temperatures within the range $0 - 80°C$ on the maturity of concrete may be taken into account by adjusting the concrete age according to the following Expression:

$$t_T = \sum_{i=1}^{n} e^{-(4000/[273 + T(\Delta t_i)] - 13,65)} \cdot \Delta t_i$$

(B.10)

where:
    t_T is the temperature adjusted concrete age which replaces t in the corresponding equations
    $T(\Delta t_i)$ is the temperature in °C during the time period Δt_i
    Δt_i is the number of days where a temperature T prevails.

The mean coefficient of variation of the above predicted creep data, deduced from a computerised data bank of laboratory test results, is of the order of 20%.

The values of $\varphi\,(t,t_0)$ given above should be associated with the tangent modulus E_c.
When a less accurate estimate is considered satisfactory, the values given in Figure 3.1 of 3.1.4 may be adopted for creep of concrete at 70 years.

B.2   Basic equations for determining the drying shrinkage strain

(1) The basic drying shrinkage strain $\varepsilon_{cd,0}$ is calculated from

$$\varepsilon_{cd,0} = 0{,}85\left[(220+110\cdot\alpha_{ds1})\cdot\exp\left(-\alpha_{ds2}\cdot\frac{f_{cm}}{f_{cmo}}\right)\right]\cdot10^{-6}\cdot\beta_{RH} \tag{B.11}$$

$$\beta_{RH} = 1{,}55\left[1-\left(\frac{RH}{RH_0}\right)^3\right] \tag{B.12}$$

where:
   f_{cm} is the mean compressive strength (MPa)
   f_{cmo} = 10 Mpa
   α_{ds1} is a coefficient which depends on the type of cement (see 3.1.2 (6))
         = 3 for cement Class S
         = 4 for cement Class N
         = 6 for cement Class R
   α_{ds2} is a coefficient which depends on the type of cement
         = 0,13 for cement Class S
         = 0,12 for cement Class N
         = 0,11 for cement Class R
   RH is the ambient relative humidity (%)
   RH_0 = 100%.

   Note: exp{ } has the same meaning as $e^{(\ )}$

ANNEX C (Normative)

Properties of reinforcement suitable for use with this Eurocode

C.1 General

(1) Table C.1 gives the properties of reinforcement suitable for use with this Eurocode. The properties are valid for temperatures between -40ºC and 100ºC for the reinforcement in the finished structure. Any bending and welding of reinforcement carried out on site should be further restricted to the temperature range as permitted by EN 13670.

Table C.1: Properties of reinforcement

Product form	Bars and de-coiled rods			Wire Fabrics			Requirement or quantile value (%)
Class	A	B	C	A	B	C	-
Characteristic yield strength f_{yk} or $f_{0,2k}$ (MPa)	400 to 600						5,0
Minimum value of $k = (f_t/f_y)_k$	≥1,05	≥1,08	≥1,15 <1,35	≥1,05	≥1,08	≥1,15 <1,35	10,0
Characteristic strain at maximum force, ε_{uk} (%)	≥2,5	≥5,0	≥7,5	≥2,5	≥5,0	≥7,5	10,0
Bendability	Bend/Rebend test			-			
Shear strength	-			0,3 A f_{yk} (A is area of wire)			Minimum
Maximum deviation from nominal mass (individual bar or wire) (%) — Nominal bar size (mm) ≤ 8 / > 8	± 6,0 ± 4,5						5,0

Note: The values for the fatigue stress range with an upper limit of βf_{yk} and for the Minimum relative rib area for use in a Country may be found in its National Annex. The recommended values are given in Table C.2N. The value of β for use in a Country may be found in its National Annex. The recommended value is 0,6.

Table C.2N: Properties of reinforcement

Product form	Bars and de-coiled rods			Wire Fabrics			Requirement or quantile value (%)
Class	A	B	C	A	B	C	-
Fatigue stress range (MPa) (for N ≥ 2 x 10^6 cycles) with an upper limit of βf_{yk}	≥150			≥100			10,0
Bond: Minimum relative rib area, $f_{R,min}$ — Nominal bar size (mm) 5 - 6 / 6,5 to 12 / > 12	0,035 0,040 0,056						5,0

Fatigue: Exceptions to the fatigue rules for use in a Country may be found in its National Annex. The

recommended exceptions are if the reinforcement is for predominantly static loading or higher values of the fatigue stress range and/or the number of cycles are shown to apply by testing. In the latter case the values in Table 6.3 may be modified accordingly. Such testing should be in accordance with EN 10080.

Bond: Where it can be shown that sufficient bond strength is achievable with f_R values less than specified above, the values may be relaxed. In order to ensure that sufficient bond strength is achieved, the bond stresses shall satisfy the recommended Expressions (C.1N) and (C.2N) when tested using the CEB/RILEM beam test:

$$\tau_m \geq 0,098 \ (80 - 1,2\phi) \tag{C.1N}$$

$$\tau_r \geq 0,098 \ (130 - 1,9\phi) \tag{C.2N}$$

where:
$\quad\phi\quad$ is the nominal bar size (mm)
$\quad\tau_m\quad$ is the mean value of bond stress (MPa) at 0,01, 0,1 and 1 mm slip
$\quad\tau_r\quad$ is the bond stress at failure by slipping

(2) The values of f_{yk}, k and ε_{uk} in Table C.1 are characteristic values. The maximum % of test results falling below the characteristic value is given for each of the characteristic values in the right hand column of Table C.1.

(3) EN10080 does not specify the quantile value for characteristic values, nor the evaluation of test results for individual test units.

In order to be deemed to comply with the long term quality levels in Table C.1, the following limits on test results should be applied:
- where all individual test results of a test unit exceed the characteristic value, (or are below the characteristic value in the case the maximum value of f_{yk} or k) the test unit may be assumed to comply.
- the individual values of yield strength f_{yk}, k and ε_{uk} should be greater than the minimum values and less than the maximum values. In addition, the mean value, M, of a test unit should satisfy the equation

$$M \geq C_v + a \tag{C.3}$$

where
$\quad C_v \quad$ is the long term characteristic value
$\quad a \quad$ is a coefficient which depends on the parameter considered

Note 1: The value of a for use in a Country may be found in its National Annex. The recommended value for f_{yk} is 10 MPa and for both k and ε_{uk} is 0.

Note 2: The minimum and maximum values of f_{yk}, k and ε_{uk} for use in a Country may be found in its National Annex. The recommended values are given in Table C.3N.

Table C.3N. Absolute limits on test results

Performance characteristic	Minimum value	Maximum value
Yield strength f_{yk}	0,97 x minimum C_v	1,03 x maximum C_v
K	0,98 x minimum C_v	1,02 x maximum C_v
ε_{uk}	0,80 x minimum C_v	Not applicable

C.2 Strength

(1)P The maximum actual yield stress $f_{y,max}$ shall not exceed $1{,}3f_{yk}$.

C.3 Bendability

(1)P Bendability shall be verified by the bend and rebend tests in accordance with EN 10080 and EN ISO 15630-1. In situations where verification is carried out just using a rebend test the mandrel size shall be no greater than that specified for bending in Table 8.1 of this Eurocode. In order to ensure bendability no cracking shall be visible after the first bend.

ANNEX D (Informative)

Detailed calculation method for prestressing steel relaxation losses

D.1   General

(1) In the case that the relaxation losses are calculated for different time intervals (stages) where the stress in the prestressing tendon is not constant, for example due to the elastic shortening of the concrete, an equivalent time method should be adopted.

(2) The concept of the equivalent time method is presented in the Figure D.1, where at time t_i there is an instantaneous deformation of the prestressing tendon, with:

$\sigma_{p,i}^{-}$ is the tensile stress in the tendon just before t_i

$\sigma_{p,i}^{+}$ is the tensile stress in the tendon just after t_i

$\sigma_{p,i-1}^{+}$ is the tensile stress in the tendon at the preceding stage

$\Delta\sigma_{pr, i-1}$ is the absolute value of the relaxation loss during the preceding stage

$\Delta\sigma_{pr,i}$ is the absolute value of the relaxation loss of the stage considered
Figure D.1: Equivalent time method

(3)   Let $\displaystyle\sum_{1}^{i-1}\Delta\sigma_{pr,j}$ be the sum of all the relaxation losses of the preceding stages and t_e is defined as the equivalent time (in hours) necessary to obtain this sum of relaxation losses that verifies the relaxation time functions in 3.3.2 (7) with an initial stress equal to $\sigma_{p,i}^{+} +\displaystyle\sum_{1}^{i-1}\Delta\ \sigma_{pr, j}$

and with $\mu =\dfrac{\sigma_{p,i}^{+}+\displaystyle\sum_{1}^{i-1}\Delta\ \sigma_{pr, j}}{f_{pk}}$.

(4) For example, for a Class 2 prestressing tendon t_e, given by Expression (3.31), becomes:

$$\sum_{1}^{i-1} \Delta\sigma_{pr,\,j} \;=\; 0{,}66 \;\; \rho_{1000} \;\; e^{9{,}09\,\mu} \;\; \left(\frac{t_e}{1000}\right)^{0{,}75\,(1-\mu)} \left\{\sigma_{p,i}^{+} + \sum_{1}^{i-1}\Delta\;\sigma_{pr,\,j}\right\} \; 10^{-5} \qquad\qquad \text{(D.1)}$$

(5) After resolving the above equation for t_e, the same formula can be applied in order to estimate the relaxation loss of the stage considered, $\Delta\sigma_{pr,\,i}$ (where the equivalent time t_e is added to the interval of time considered):

$$\Delta\sigma_{pr,\,i} \;=\; 0{,}66 \;\; \rho_{1000} \;\; e^{9{,}09\,\mu} \;\; \left(\frac{t_e + \Delta\;t_i}{1000}\right)^{0{,}75\,(1-\mu)} \left\{\sigma_{p,i}^{+} + \sum_{1}^{i-1}\Delta\;\sigma_{pr,\,j}\right\} \; 10^{-5} - \sum_{1}^{i-1}\Delta\;\sigma_{pr,\,j} \qquad \text{(D.2)}$$

(6) The same principle applies for all three classes of prestressing tendons.

Annex E (Informative)

Indicative strength classes for durability

E.1   General

(1) The choice of adequately durable concrete for corrosion protection of reinforcement and protection of concrete attack, requires consideration of the composition of concrete. This may result in a higher compressive strength of the concrete than is required for structural design. The relationship between concrete strength classes and exposure classes (see Table 4.1) may be described by indicative strength classes.

(2) When the chosen strength is higher than that required for structural design the value of f_{ctm} should be associated with the higher strength in the calculation of minimum reinforcement according to 7.3.2 and 9.1.1.1 and crack width control according to 7.3.3 and 7.3.4.

Note: Values of indicative strength classes for use in a Country may be found in its National Annex. The recommended values are given in Table E.1N.

Table E.1N: Indicative strength classes

	Exposure Classes according to Table 4.1								
Corrosion									
	Carbonation-induced corrosion				Chloride-induced corrosion			Chloride-induced corrosion from sea-water		
	XC1	XC2	XC3	XC4	XD1	XD2	XD3	XS1	XS2	XS3
Indicative Strength Class	C20/25	C25/30	C30/37		C30/37		C35/45	C30/37	C35/45	
Damage to Concrete									
	No risk	Freeze/Thaw Attack			Chemical Attack					
	X0	XF1	XF2	XF3	XA1	XA2	XA3			
Indicative Strength Class	C12/15	C30/37	C25/30	C30/37	C30/37		C35/45			

Annex F (Informative)

Tension reinforcement expressions for in-plane stress conditions

F.1   General

(1) This annex does not include expressions for compression reinforcement.

(2) The tension reinforcement in an element subject to in-plane orthogonal stresses σ_{Edx}, σ_{Edy} and τ_{Edxy} may be calculated using the procedure set out below. Compressive stresses should be taken as positive, with $\sigma_{Edx} > \sigma_{Edy}$, and the direction of reinforcement should coincide with the x and y axes.

The tensile strengths provided by reinforcement should be determined from:

$$f_{tdx} = \rho_x \, f_{yd} \ \text{ and } \ f_{tdy} = \rho_y \, f_{yd} \tag{F.1}$$

where ρ_x and ρ_y are the geometric reinforcement ratios, along the x and y axes respectively.

(3) In locations where σ_{Edx} and σ_{Edy} are both compressive and $\sigma_{Edx} \cdot \sigma_{Edy} > \tau^2_{Edxy}$, design reinforcement is not required. However the maximum compressive stress should not exceed f_{cd} (See 3.1.6)

(4) In locations where σ_{Edy} is tensile or $\sigma_{Edx} \cdot \sigma_{Edy} \leq \tau^2_{Edxy}$, reinforcement is required.

The optimum reinforcement, indicated by superscript ′, and related concrete stress are determined by:

For $\sigma_{Edx} \leq |\tau_{Edxy}|$

$$f'_{tdx} = |\tau_{Edxy}| - \sigma_{Edx} \tag{F.2}$$
$$f'_{tdy} = |\tau_{Edxy}| - \sigma_{Edy} \tag{F.3}$$
$$\sigma_{cd} = 2|\tau_{Edy}| \tag{F.4}$$

For $\sigma_{Edx} > |\tau_{Edxy}|$

$$f'_{tdx} = 0 \tag{F.5}$$
$$f'_{tdy} = \frac{\tau^2_{Edxy}}{\sigma_{Edx}} - \sigma_{Edy} \tag{F.6}$$
$$\sigma_{cd} = \sigma_{Edx}\left(1 + \left(\frac{\tau_{Edxy}}{\sigma_{Edx}}\right)^2\right) \tag{F.7}$$

The concrete stress, σ_{cd}, should be checked with a realistic model of cracked sections (see EN 1992-2), but should not generally exceed νf_{cd} (ν may be obtained from Expression (6.5).

> **Note:** The minimum reinforcement is obtained if the directions of reinforcement are identical to the directions of the principal stresses.

Alternatively, for the general case the necessary reinforcement and the concrete stress may be

determined by:

$$f_{tdx} = |\tau_{Edxy}| \cot\theta - \sigma_{Edx} \tag{F.8}$$

$$f_{tdy} = |\tau_{Edxy}|/\cot\theta - \sigma_{Edy} \tag{F.9}$$

$$\sigma_{cd} = |\tau_{Edxy}| \left(\cot\theta + \frac{1}{\cot\theta} \right) \tag{F.10}$$

where θ is the angle of the principal concrete compressive stress to the *x*-axis.

Note: The value of $\cot\theta$ should be chosen to avoid compression values of f_{td}.

In order to avoid unacceptable cracks for the serviceability limit state, and to ensure the required deformation capacity for the ultimate limit state, the reinforcement derived from Expressions (F.8) and (F.9) for each direction should not be more than twice and not less than half the reinforcement determined by expressions (F2) and (F3) or (F5) and (F6). These limitations are expressed by $\frac{1}{2}f'_{tdx} \leq f_{tdx} \leq 2f'_{tdx}$ and $\frac{1}{2}f'_{tdy} \leq f_{tdy} \leq 2f'_{tdy}$.

(5) The reinforcement should be fully anchored at all free edges, e.g. by U-bars or similar.

Annex G (Informative)

Soil structure interaction

G.1 Shallow foundations

G.1.1 General

(1)   The interaction between the ground, the foundation and the superstructure should be considered. The contact pressure distribution on the foundations and the column forces are both dependent on the relative settlements.

(2) In general the problem may be solved by ensuring that the displacements and associated reactions of the soil and the structure are compatible.

(3) Although the above general procedure is adequate, many uncertainties still exist, due to the load sequence and creep effects. For this reason different levels of analysis, depending on the degree of idealisation of the mechanical models, are usually defined.

(4) If the superstructure is considered as flexible, then the transmitted loads do not depend on the relative settlements, because the structure has no rigidity. In this case the loads are no longer unknown, and the problem is reduced to the analysis of a foundation on a deforming ground.

(5) If the superstructure is considered as rigid, then the unknown foundation loads can be obtained by the condition that settlements should lie on a plane. It should be checked that this rigidity exists until the ultimate limit state is reached.

(6)   A further simplifying scheme arises if the foundation system can be assumed to be rigid or the supporting ground is very stiff. In either case the relative settlements may be ignored and no modification of the loads transmitted from the superstructure is required.

(7) To determine the approximate rigidity of the structural system, an analysis may be made comparing the combined stiffness of the foundation, superstructure framing members and shear walls, with the stiffness of the ground. This relative stiffness K_R will determine whether the foundation or the structural system should be considered rigid or flexible. The following expression may be used for building structures:

$$K_R = (EJ)_S / (EI^3)$$
(G.1)

where:

$(EJ)_S$ is the approximate value of the flexural rigidity per unit width of the building structure under consideration, obtained by summing the flexural rigidity of the foundation, of each framed member and any shear wall

E is the deformation modulus of the ground

I is the length of the foundation

Relative stiffnesses higher than 0,5 indicate rigid structural systems.

213

G.1.2 Levels of analysis

(1) For design purposes, the following levels of analysis are permitted:

Level 0: In this level, linear distribution of the contact pressure may be assumed.

The following preconditions should be fulfilled:
- the contact pressure does not exceed the design values for both the serviceability and the ultimate limit states;
- at the serviceability limit state, the structural system is not affected by settlements, or the expected differential settlements are not significant;
- at the ultimate limit state, the structural system has sufficient plastic deformation capacity so that differences in settlements do not affect the design.

Level 1: The contact pressure may be determined taking into account the relative stiffness of the foundation and the soil and the resulting deformations evaluated to check that they are within acceptable limits.

The following preconditions should be fulfilled:

- sufficient experience exists to show that the serviceability of the superstructure is not likely to be affected by the soil deformation;
- at the ultimate limit state, the structural system has adequate ductile behaviour.

Level 2: At this level of analysis the influence of ground deformations on the superstructure is considered. The structure is analysed under the imposed deformation of the foundation to determine the adjustments to the loads applied to the foundations. If the resulting adjustments are significant (i.e. > $\lvert 10 \rvert$ %) then Level 3 analysis should be adopted.

Level 3: This is a complete interactive procedure taking into account the structure, its foundations and the ground.

G.2   Piled foundations

(1) If the pile cap is rigid, a linear variation of the settlements of the individual piles may be assumed which depends on the rotation of the pile cap. If this rotation is zero or may be ignored, equal settlement of all piles may be assumed. From equilibrium equations, the unknown pile loads and the settlement of the group can be calculated.

(2) However, when dealing with a piled raft, interaction occurs not only between individual piles but also between the raft and the piles, and no simple approach to analyse this problem is available.

(3) The response of a pile group to horizontal loads generally involves not only the lateral stiffness of the surrounding soil and of the piles, but also their axial stiffness (e.g. lateral load on a pile group causes tension and compression on edge piles).

Annex H (Informative)

Global second order effects in structures

H.1 Criteria for neglecting global second order effects

H.1.1 General

(1) Clause H.1 gives criteria for structures where the conditions in 5.8.3.3 (1) are not met. The criteria are based on 5.8.2 (6) and take into account global bending and shear deformations, as defined in Figure H.1.
Figure H.1: **Definition of global bending and shear deformations (1/r and γ respectively) and the corresponding stiffnesses (EI and S respectively)**

H.1.2 Bracing system without significant shear deformations

(1) For a bracing system without significant shear deformations (e.g. shear walls without openings), global second order effects may be ignored if:

$$F_{V,Ed} \leq 0{,}1 \cdot F_{V,BB} \tag{H.1}$$

where:
- $F_{V,Ed}$ is the total vertical load (on braced and bracing members)
- $F_{V,BB}$ is the nominal global buckling load for global bending, see (2)

(2)   The nominal global buckling load for global bending may be taken as

$$F_{V,BB} = \xi \cdot \Sigma EI / L^2 \tag{H.2}$$

where:
- ξ is a coefficient depending on number of storeys, variation of stiffness, rigidity of base restraint and load distribution; see (4)

ΣEI is the sum of bending stiffnesses of bracing members in direction considered, including possible effects of cracking; see (3)

L is the total height of building above level of moment restraint.

(3) In the absence of a more accurate evaluation of the stiffness, the following may be used for a bracing member with *cracked* section:

$$EI \approx 0{,}4\,E_{cd}I_c \tag{H.3}$$

where:

E_{cd} $= E_{cm}/\gamma_{cE}$, design value of concrete modulus, see 5.8.6 (3)

I_c second moment of area of bracing member

If the cross-section is shown to be *uncracked* in the ultimate limit state, constant 0,4 in Expression (H.3) may be replaced by 0,8.

(4) If bracing members have constant stiffness along the height and the total vertical load increases with the same amount per storey, then ξ may be taken as

$$\xi = 7{,}8 \cdot \frac{n_s}{n_s + 1{,}6} \cdot \frac{1}{1 + 0{,}7 \cdot k} \tag{H.4}$$

where:

n_s is the number of storeys

k is the relative flexibility of moment restraint; see (5).

(5) The relative flexibility of moment restraint at the base is defined as:

$$k = (\theta/M)\cdot(EI/L) \tag{H.5}$$

where:

θ is the rotation for bending moment M

EI is the stiffness according to (3)

L is the otal height of bracing unit

Note: For $k = 0$, i.e. rigid restraint, Expressions (H.1)-(H.4) can be combined into Expression (5.18), where the coefficient 0,31 follows from $0{,}1 \cdot 0{,}4 \cdot 7{,}8 \approx 0{,}31$.

.

H.1.3 Bracing system with significant global shear deformations

(1) Global second order effects may be ignored if the following condition is fulfilled:

$$F_{V,Ed} \leq 0{,}1 \cdot F_{V,B} = 0{,}1 \cdot \frac{F_{V,BB}}{1 + F_{V,BB} / F_{V,BS}} \tag{H.6}$$

where

$F_{V,B}$ is the global buckling load taking into account global bending *and* shear

$F_{V,BB}$ is the global buckling load for pure bending, see H.1.2 (2)

$F_{V,BS}$ is the global buckling load for pure shear, $F_{V,BS} = \Sigma S$

ΣS is the total shear stiffness (force per shear angle) of bracing units (see Figure H.1)

Note: The global shear deformation of a bracing unit is normally governed mainly by local bending deformations (Figure H.1). Therefore, in the absence of a more refined analysis, cracking may be taken into account for S in the same way as for EI; see H.1.2 (3).

H.2 Methods for calculation of global second order effects

(1) This clause is based on linear second order analysis according to 5.8.7. Global second order effects may then be taken into account by analysing the structure for fictitious, magnified horizontal forces $F_{H,Ed}$:

$$F_{H,Ed} = \frac{F_{H,0Ed}}{1 - F_{V,Ed} / F_{V,B}}$$

(H.7)

where:

 $F_{H,0Ed}$ is the first order horizontal force due to wind, imperfections etc.
 $F_{V,Ed}$ is the total vertical load on bracing *and* braced members
 $F_{V,B}$ is the nominal global buckling load, see (2).

(2) The buckling load $F_{V,B}$ may be determined according to H.1.3 (or H.1.2 if global shear deformations are negligible). However, in this case nominal stiffness values according to 5.8.7.2 should be used, including the effect of creep.

(3) In cases where the global buckling load $F_{V,B}$ is not defined, the following expression may be used instead:

$$F_{H,Ed} = \frac{F_{H,0Ed}}{1 - F_{H,1Ed} / F_{H,0Ed}}$$

(H.8)

where:

 $F_{H,1Ed}$ fictitious horizontal force, giving the same bending moments as vertical load $N_{V,Ed}$ acting on the deformed structure, with deformation caused by $F_{H,0Ed}$ (first order deformation), and calculated with nominal stiffness values according to 5.8.7.2

Note: Expression (H.8) follows from a step-by-step numerical calculation, where the effect of vertical load and deformation increments, expressed as equivalent horizontal forces, are added in consecutive steps. The increments will form a geometric series after a few steps. Assuming that this occurs even at the first step, (which is analogous to assuming β =1 in 5.8.7.3 (3)), the sum can be expressed as in Expression (H.8). This assumption requires that the stiffness values representing the final stage of deformations are used in all steps (note that this is also the basic assumption behind the analysis based on nominal stiffness values).

In other cases, e.g. if uncracked sections are assumed in the first step and cracking is found to occur in later steps, or if the distribution of equivalent horizontal forces changes significantly between the first steps, then more steps have to be included in the analysis, until the assumption of a geometric series is met. Example with two more steps than in Expression (H.8):

$F_{H,Ed} = F_{H,0Ed} + F_{H,1Ed} + F_{H,2Ed} /(1- F_{H,3Ed} / F_{H,2Ed})$

Annex I (Informative)

Analysis of flat slabs and shear walls

I.1 Flat Slabs

I.1.1 General

(1) For the purpose of this section flat slabs may be of uniform thickness or they may incorporate drops (thickenings over columns).

(2) Flat slabs should be analysed using a proven method of analysis, such as grillage (in which the plate is idealised as a set of interconnected discrete members), finite element, yield line or equivalent frame. Appropriate geometric and material properties should be employed.

I.1.2 Equivalent frame analysis

(1) The structure should be divided longitudinally and transversely into frames consisting of columns and sections of slabs contained between the centre lines of adjacent panels (area bounded by four adjacent supports). The stiffness of members may be calculated from their gross cross-sections. For vertical loading the stiffness may be based on the full width of the panels. For horizontal loading 40% of this value should be used to reflect the increased flexibility of the column/slab joints in flat slab structures compared to that of column/beam joints. Total load on the panel should be used for the analysis in each direction.

(2) The total bending moments obtained from analysis should be distributed across the width of the slab. In elastic analysis negative moments tend to concentrate towards the centre lines of the columns.

(3) The panels should be assumed to be divided into column and middle strips (see Figure I.1) and the bending moments should be apportioned as given in Table I.1.

Figure I.1: Division of panels in flat slabs

Note: When drops of width > (l_y/3) are used the column strips may be taken to be the width of drops. The width of middle strips should then be adjusted accordingly.

Table I.1 Simplified apportionment of bending moment for a flat slab

	Negative moments	**Positive moments**
Column Strip	60 - 80%	50 - 70%
Middle Strip	40 - 20%	50 - 30%
Note: Total negative and positive moments to be resisted by the column and middle strips together should always add up to 100%.		

(4) Where the width of the column strip is different from $0,5l_x$ as shown in Figure I.1 (e.g.) and made equal to width of drop the width of middle strip should be adjusted accordingly.

(5) Unless there are perimeter beams, which are adequately designed for torsion, moments transferred to edge or corner columns should be limited to the moment of resistance of a rectangular section equal to $0,17\ b_e d^2\ f_{ck}$ (see Figure 9.9 for the definition of b_e). The positive moment in the end span should be adjusted accordingly.

I.1.3 Irregular column layout

(1) Where, due to the irregular layout of columns, a flat slab can not be sensibly analysed using the equivalent frame method, a grillage or other elastic method may be used. In such a case the following simplified approach will normally be sufficient:
   i) analyse the slab with the full load, $\gamma_Q Q_k + \gamma_G G_k$, on all bays
   ii) the midspan and column moments should then be increased to allow for the effects of pattern loads. This may be achieved by loading a critical bay (or bays) with $\gamma_Q Q_k + \gamma_G G_k$ and the rest of the slab with $\gamma_G G_k$. Where there may be significant variation in the permanent load between bays, γ_G should be taken as 1 for the unloaded bays.
   iii) the effects of this particular loading may then be applied to other critical bays and supports in a similar way.

(2) The restrictions with regard to the transfer of moments to edge columns given in 5.11.2 should be applied.

I.2 Shear Walls

(1) Shear walls are plain or reinforced concrete walls which contribute to the lateral stability of the structure.

(2) Lateral load resisted by each shear wall in a structure should be obtained from a global analysis of the structure, taking into account the applied loads, the eccentricities of the loads with respect to the shear centre of the structure and the interaction between the different structural walls.

(3) The effects of asymmetry of wind loading should be considered (see EN 1991-1-4).

(4) The combined effects of axial loading and shear should be taken into account.

(5) In addition to other serviceability criteria in this code, the effect of sway of shear walls on the occupants of the structure should also be considered, (see EN 1990).

(6) In the case of building structures not exceeding 25 storeys, where the plan layout of the walls is reasonably symmetrical, and the walls do not have openings causing significant global shear deformations, the lateral load resisted by a shear wall may be obtained as follows:

$$P_n = \frac{P(EI)_n}{\Sigma(EI)} \pm \frac{(Pe)y_n(EI)_n}{\Sigma(EI)y_n^2}$$

(I.1)

where:
   P_n is the lateral load on wall n
   $(EI)_n$ is the stiffness of wall n
   P is the applied load
   e is the eccentricity of P with respect to the centroid of the stiffnesses (see Figure I.3)
   y_n is the distance of wall n from the centroid of stiffnesses.

(7) If members with and without significant shear deformations are combined in the bracing system, the analysis should take into account both shear and flexural deformation.

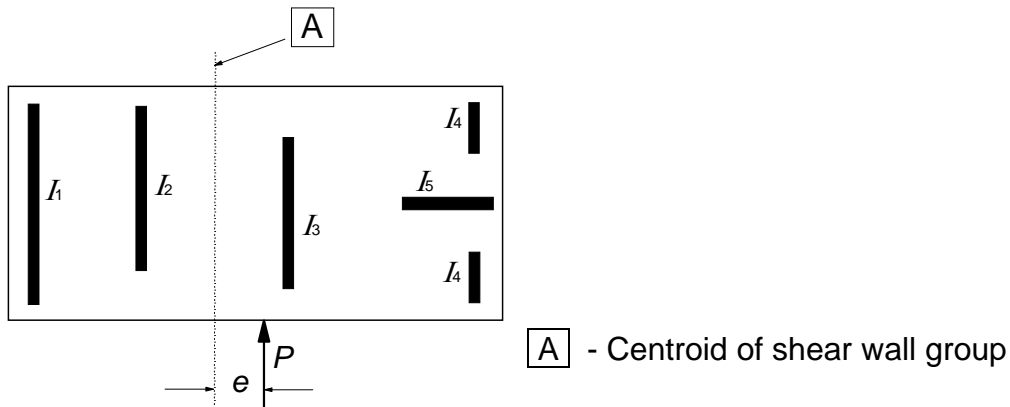

Figure I.3: Eccentricity of load from centroid of shear walls

Annex J (Informative)

Detailing rules for particular situations

J.1   Surface reinforcement

(1) Surface reinforcement to resist spalling should be used where the main reinforcement is made up of:
-   bars with diameter greater than 32 mm or
-   bundled bars with equivalent diameter greater than 32 mm (see 8.8)

The surface reinforcement should consist of wire mesh or small diameter bars, and be placed outside the links as indicated in Figure J.1.
x is the depth of the neutral axis at ULS

Figure J.1: Example of surface reinforcement

(2) The area of surface reinforcement $A_{s,surf}$ should be not less than $A_{s,surfmin}$ in the two directions parallel and orthogonal to the tension reinforcement in the beam,

Note: The value of $A_{s,surfmin}$ for use in a Country may be found in its National Annex. The recommended value is 0,01 $A_{ct,ext}$, where $A_{ct,ext}$ is the area of the tensile concrete external to the links (see Figure 9.7).

(3) Where the cover to reinforcement is greater than 70 mm, for enhanced durability similar surface reinforcement should be used, with an area of 0,005 $A_{ct,ext}$ in each direction.

(4) The minimum cover needed for the surface reinforcement is given in 4.4.1.2.

(5) The longitudinal bars of the surface reinforcement may be taken into account as longitudinal bending reinforcement and the transverse bars as shear reinforcement provided that they meet the requirements for the arrangement and anchorage of these types of reinforcement.

J.2   Frame corners

J.2.1   General

(1) The concrete strength $\sigma_{Rd,max}$ should be determined with respect to 6.5.2 (compression zones with or without transverse reinforcement).

J.2.2 Frame corners with closing moments

(1) For approximately equal depths of column and beam ($2/3 < h_2/h_1 < 3/2$) (see Figure J.2 (a)) no check of link reinforcement or anchorage lengths within the beam column joint is required, provided that all the tension reinforcement of the beam is bent around the corner.

(2) Figure J.2 (b) shows a strut and tie model for $h_2/h_1 < 2/3$ for a limited range of $\tan\theta$.

Note: The values of the limits of $\tan\theta$ for use in a Country may be found in its National Annex. The recommended value of the lower limit is 0,4 and the recommended value of the upper limit is 1.

(3) The anchorage length l_{bd} should be determined for the force $\Delta F_{td} = F_{td2} - F_{td1}$.

(4) Reinforcement should be provided for transverse tensile forces perpendicular to an in-plane node.
(a) almost equal depth of beam and column
(b) very different depth of beam and column

Figure J.2: Frame Corner with closing moment. Model and reinforcement

J.2.3 Frame corners with opening moments

(1) For approximately equal depths of column and beam the strut and tie models given in Figures J.3 (a) and J.4 (a) may be used. Reinforcement should be provided as a loop in the corner region or as two overlapping U bars in combination with inclined links as shown in Figures J.3 (b) and (c) and Figures J.4 (b) and (c).

a) strut and tie model   **(b) and (c) detailing of reinforcement**
Figure J.3: Frame corner with moderate opening moment (e.g. $A_S/bh \le 2\%$)

(2) For large opening moments a diagonal bar and links to prevent splitting should be considered as shown in Figure J.4.

a) strut-and-tie model   **(b) and (c) detailing of reinforcement**
Figure J.4: Frame corner with large opening moment (e.g. $A_S/bh > 2\%$)

J.3   Corbels

(1) Corbels ($a_c < z_0$) may be designed using strut-and-tie models as described in 6.5 (see Figure J.5). The inclination of the strut is limited by $1,0 \leq \tan\theta \leq 2,5$.
Figure J.5: Corbel strut-and-tie model

(2) If $a_c < 0,5\ h_c$ closed horizontal or inclined links with $A_{s,lnk} \geq k_1\ A_{s,main}$ should be provided in addition to the main tension reinforcement (see Figure J.6 (a)).

> **Note:** The value of k_1 for use in a Country may be found in its National Annex. The recommended value is 0,25.

(3) If $a_c > 0,5\ h_c$ and $F_{Ed} > V_{Rd,c}$ (see 6.2.2), closed vertical links $A_{s,lnk} \geq k_2\ F_{Ed}/f_{yd}$ should be provided in addition to the main tension reinforcement (see Figure J.6 (b)).

> **Note:** The value of k_2 for use in a Country may be found in its National Annex. The recommended value is 0,5.

(4) The main tension reinforcement should be anchored at both ends. It should be anchored in the supporting element on the far face and the anchorage length should be measured from the location of the vertical reinforcement in the near face. The reinforcement should be anchored in the corbel and the anchorage length should be measured from the inner face of the loading plate.

(5) If there are special requirements for crack limitation, inclined stirrups at the re-entrant opening will be effective.

$$\Sigma A_{s,lnk} \geq A_{s,main}$$

$$A_{s,lnk} \geq k_1 A_{s,main}$$
$\boxed{A}$ - anchorage devices or loops $\boxed{B}$ - Links

(a) reinforcement for $a_c \leq 0,5\ h_c$ **(b) reinforcement for $a_c > 0,5\ h_c$**

 Contents List

Note: This contents list includes sections and clauses that have been introduced or modified in EN 1992-2.

Annexes

Note: This contents list includes annexes that have been introduced or modified in EN 1992-2.

Foreword

This European Standard EN 1992, Eurocode 2, Part 2: Design of concrete structures: Concrete bridges - Design and detailing rules, has been prepared on behalf of Technical Committee CEN/TC250 « Structural Eurocodes », the Secretariat of which is held by BSI. CEN/TC250 is responsible for all Structural Eurocodes.

This Eurocode supersedes ENV 1992-2.

Background to the Eurocode programme

See EN 1992-1-1.

Status and field of application of Eurocodes

See EN 1992-1-1.

National Standards implementing Eurocodes

See EN 1992-1-1.

Links between Eurocodes and harmonised technical specifications (ENs and ETAs) for products

See EN 1992-1-1.

Additional information specific to EN 1992-2 and link to EN 1992-1-1

EN 1992-2 describes the principles and requirements for safety, serviceability and durability of concrete structures, together with specific provisions for bridges. It is based on the limit state concept used in conjunction with a partial factor method.
–   EN 1992 -2 gives Principles and Application Rules for the design of bridges in addition to those stated in EN 1992 - 1- 1. All relevant clauses of EN 1992-1-1 are applicable to the design of bridges unless specifically deleted or varied by EN 1992 - 2. It has been appropriate to introduce in EN 1992 -2 some material, in the form of new clauses or amplifications of clauses in EN 1992-1-1,which is not bridge specific and which strictly belongs to EN 1992-1-1. These new clauses and amplifications are deemed valid interpretations of EN 1992-1 -1 and designs complying with the requirements of EN 1992 -2 are deemed to comply with the Principles of EN 1992 -1 -1.
–   clauses in EN 1992–2 that modify those in EN 1992–1–1 are numbered by adding '100' to the corresponding clause number in EN 1992–1–1.
–   when additional clauses or sub-clauses are introduced in EN 1992–2, these are numbered by adding '101' to the last relevant clause or sub-clause in EN 1992–1–1.

For the design of new structures, EN 1992-2 is intended to be used, for direct application, together with other parts of EN 1992, Eurocodes EN 1990,1991, 1997 and 1998.

EN 1992-2 also serves as a reference document for other CEN TCs concerning structural matters.

EN 1992-2 is intended for use by:
–   committees drafting other standards for structural design and related product, testing and execution standards;
–   clients (e.g. for the formulation of their specific requirements on reliability levels and durability);
–   designers and constructors ;
–   relevant authorities.

Numerical values for partial factors and other reliability parameters are recommended as basic values that provide an acceptable level of reliability. They have been selected assuming that an appropriate level of workmanship and of quality management applies. When EN 1992-2 is used as a base document by other CEN/TCs the same values need to be taken.

National annex for EN 1992-2

This standard gives values with notes indicating where national choices may have to be made. Therefore the National Standard implementing EN 1992-2 should have a National annex containing all Nationally Determined Parameters to be used for the design of bridges to be constructed in the relevant country.

National choice is allowed in EN1992-2 through the following clauses:

3.1.2 (102)P	5.3.2.2 (104)	6.8.7 (101)	9.1 (103)
3.1.6 (101)P	5.5 (104)	7.2 (102)	9.2.2 (101)
3.1.6 (102)P	5.7 (105)	7.3.1 (105)	9.5.3 (101)
3.2.4 (101)P	6.1 (110)	7.3.3 (101)	9.7 (102)
4.2 (105)	6.2.2 (101)	7.3.4 (101)	9.8.1 (103)
4.2 (106)	6.2.3 (103)	8.9.1 (101)	11.9 (101)
4.4.1.2 (109)	6.2.3 (107)	8.10.4 (105)	113.2 (102)
5.1.3 (101)P	6.2.3 (109)	8.10.4 (107)	113.3.2 (103)
5.2 (105)	6.8.1 (102)		

SECTION 1 GENERAL

The following clauses of EN 1992-1-1 apply.

1.1.1 (1)P	1.1.2 (3)P	1.2.2	1.5.2.1
1.1.1 (2)P	1.1.2 (4)P	1.3 (1)P	1.5.2.2
1.1.1 (3)P	1.2 (1)P	1.4 (1)P	1.5.2.3
1.1.1 (4)P	1.2.1	1.5.1 (1)P	1.5.2.4

1.1 Scope

1.1.2 Scope of Part 2 of Eurocode 2

(101)P Part 2 of Eurocode 2 gives a basis for the design of bridges in plain, reinforced and prestressed concrete made with normal and light weight aggregates.

(102)P The following subjects are dealt with in Part 2.

Section 1:   General
Section 2:   Basis of design
Section 3:   Materials
Section 4:   Durability and cover to reinforcement
Section 5:   Structural analysis
Section 6:   Ultimate limit states
Section 7:   Serviceability limit states
Section 8:   Detailing of reinforcement and prestressing tendons - General
Section 9:   Detailing of members and particular rules
Section 10:   Additional rules for precast concrete elements and structures
Section 11:   Lightweight aggregate concrete structures
Section 12:   Plain and lightly reinforced concrete structures
Section 13:   Design for the execution stages

1.106 Symbols

For the purposes of this standard, the following symbols apply.

> **Note:** The notation used is based on ISO 3898:1987. Symbols with unique meaning have been used as far as possible. However, in some instances a symbol may have more than one meaning depending on the context.

Latin upper case letters

A Accidental action
A Cross sectional area
A_c Cross sectional area of concrete
A_{ct} Area of concrete in tensile zone
A_p Area of a prestressing tendon or tendons
A_s Cross sectional area of reinforcement
$A_{s,min}$ minimum cross sectional area of reinforcement
A_{sw} Cross sectional area of shear reinforcement
D Diameter of mandrel
D_{Ed} Fatigue damage factor

E Effect of action

E_c, $E_{c(28)}$ Tangent modulus of elasticity of normal weight concrete at a stress of $\sigma_c = 0$ and at 28 days

$E_{c,eff}$ Effective modulus of elasticity of concrete

E_{cd} Design value of modulus of elasticity of concrete

E_{cm} Secant modulus of elasticity of concrete

$E_c(t)$ Tangent modulus of elasticity of normal weight concrete at a stress of $\sigma_c = 0$ and at time t

E_p Design value of modulus of elasticity of prestressing steel

E_s Design value of modulus of elasticity of reinforcing steel

EI Bending stiffness

EQU   Static equilibrium

F Action

F_d Design value of an action

F_k Characteristic value of an action

G_k Characteristic permanent action

I Second moment of area of concrete section

J creep function

K_c Factor for cracking and creep effects

K_s Factor for reinforcement contribution

L Length

M Bending moment

M_{Ed} Design value of the applied internal bending moment

M_{rep} Cracking bending moment

N Axial force or number of cyclic loads in fatigue

N_{Ed} Design value of the applied axial force (tension or compression)

P Prestressing force

P_0 Initial force at the active end of the tendon immediately after stressing

Q_k Characteristic variable action

Q_{fat} Characteristic fatigue load

R Resistance or relaxation function

S Internal forces and moments

S First moment of area

SLS   Serviceability limit state

T Torsional moment

T_{Ed} Design value of the applied torsional moment

ULS   Ultimate limit state

V Shear force

V_{Ed} Design value of the applied shear force

Vol Volume of traffic

Latin lower case letters

a Distance

a Geometrical data

Δa Deviation for geometrical data

b Overall width of a cross-section, or actual flange width in a T or L beam

b_w Width of the web on T, I or L beams

c_{min} Minimum cover

d Diameter ; Depth

d Effective depth of a cross-section

d_g	Largest nominal maximum aggregate size
e	Eccentricity
f	Frequency
f_c	Compressive strength of concrete
f_{cd}	Design value of concrete compressive strength
f_{ck}	Characteristic compressive cylinder strength of concrete at 28 days
f_{cm}	Mean value of concrete cylinder compressive strength
f_{ctb}	Tensile strength prior to cracking in biaxial state of stress
f_{ctk}	Characteristic axial tensile strength of concrete
f_{ctm}	Mean value of axial tensile strength of concrete
f_p	Tensile strength of prestressing steel
f_{pk}	Characteristic tensile strength of prestressing steel
$f_{p0,1}$	0,1% proof-stress of prestressing steel
$f_{p0,1k}$	Characteristic 0,1% proof-stress of prestressing steel
$f_{0,2k}$	Characteristic 0,2% proof-stress of reinforcement
f_t	Tensile strength of reinforcement
f_{tk}	Characteristic tensile strength of reinforcement
f_y	Yield strength of reinforcement
f_{yd}	Design yield strength of reinforcement
f_{yk}	Characteristic yield strength of reinforcement
f_{ywd}	Design yield of shear reinforcement
h	Height
h	Overall depth of a cross-section
i	Radius of gyration
k	Coefficient ; Factor
l	Length, span or height
m	Mass or slab components
n	Plate components
q_{ud}	Maximum value of combination reached in non linear analysis
r	Radius or correcting factor for prestress
	$1/r$ Curvature at a particular section
s	Spacing between cracks
t	Thickness
t	Time being considered
t_0	The age of concrete at the time of loading
u	Perimeter of concrete cross-section, having area A_c
u	Component of the displacement of a point
v	Component of the displacement of a point or transverse shear
w	Component of the displacement of a point or crack width
x	Neutral axis depth
x,y,z	Coordinates
x_u	Neutral axis depth at ULS after redistribution
z	Lever arm of internal forces

Greek upper case letters

Φ	Basic creep coefficient

Greek lower case letters

α	Angle ; ratio ; long term effects coefficient or ratio between principal stresses
α_e	E_s/E_{cm} ratio

α_h Reduction factor for θ_i

β Angle ; ratio; coefficient

δ Redistributed moment ratio

γ Partial factor

γ_A Partial factor for accidental actions A

γ_C Partial factor for concrete γ_F Partial factor for actions, F

$\gamma_{F,fat}$ Partial factor for fatigue actions

$\gamma_{C,fat}$ Partial factor for fatigue of concrete

γ_{gl} Global safety factor

γ_G Partial factor for permanent actions, G

γ_M Partial factor for a material property, taking account of uncertainties in the material property itself, in geometric deviation and in the design model used

γ_P Partial factor for actions associated with prestressing, P

γ_Q Partial factor for variable actions, Q

γ_S Partial factor for reinforcing or prestressing steel

$\gamma_{S,fat}$ Partial factor for reinforcing or prestressing steel under fatigue loading

γ_f Partial factor for actions without taking account of model uncertainties

γ_g Partial factor for permanent actions without taking account of model uncertainties

γ_m Partial factors for a material property, taking account only of uncertainties in the material property

δ Increment/redistribution ratio

ξ Creep redistribution function or bond strength ratio

ζ Reduction factor/distribution coefficient

ε_c Compressive strain in the concrete

ε_{ca} Autogeneous shrinkage

ε_{cc} Creep strain

ε_{cd} Desiccation shrinkage

ε_{c1} Compressive strain in the concrete at the peak stress f_c

ε_{cu} Ultimate compressive strain in the concrete

ε_u Strain of reinforcement or prestressing steel at maximum load

ε_{uk} Characteristic strain of reinforcement or prestressing steel at maximum load

θ Angle

θ_i Inclination for geometric imperfections

λ Slenderness ratio or damage equivalent factors in fatigue

μ Coefficient of friction between the tendons and their ducts

v Poisson's ratio

v Strength reduction factor for concrete cracked in shear

ξ Ratio of bond strength of prestressing and reinforcing steel

ρ Oven-dry density of concrete in kg/m^3

ρ_{1000} Value of relaxation loss (in %), at 1000 hours after tensioning and at a mean temperature of 20°C

ρ_l Reinforcement ratio for longitudinal reinforcement

ρ_w Reinforcement ratio for shear reinforcement

σ_c Compressive stress in the concrete

σ_{cp} Compressive stress in the concrete from axial load or prestressing

σ_{cu} Compressive stress in the concrete at the ultimate compressive strain ε_{cu}

τ Torsional shear stress

ϕ Diameter of a reinforcing bar or of a prestressing duct

ϕ_n Equivalent diameter of a bundle of reinforcing bars

$\varphi(t,t_0)$ Creep coefficient, defining creep between times t and t_0 , related to elastic deformation at 28 days

φ Damage equivalent impact factor in fatigue

$\varphi(\infty,t_0)$ Final value of creep coefficient

ψ Factors defining representative values of variable actions

       ψ_0 for combination values

       ψ_1 for frequent values

       ψ_2 for quasi-permanent values

χ Ageing coefficient

SECTION 2 BASIS OF DESIGN

All the clauses of EN 1992-1-1 apply.

SECTION 3 MATERIALS

The following clauses of EN 1992-1-1 apply.

3.1.1 (1)P	*3.1.8 (1)*	*3.3.1 (1)P*	*3.3.4 (5)*
3.1.1 (2)	*3.1.9 (1)*	*3.3.1 (2)P*	*3.3.5 (1)P*

3.1.7 (3)	*3.2.7 (4)*	*3.3.4 (4)*	

3.1 Concrete

3.1.2 Strength

(102)P The strength classes (C) in this code are denoted by the characteristic cylinder strength f_{ck} determined at 28 days with a minimum value of C_{min} and a maximum value of C_{max}.

> **Note:** The values of C_{min} and C_{max} for use in a Country may be found in its National Annex. The recommended values are C30/37 and C70/85 respectively.

3.1.6 Design compressive and tensile strengths

(101)P The value of the design compressive strength is defined as

$$f_{cd} = \alpha_{cc}\, f_{ck} / \gamma_C \qquad (3.15)$$

where:

γ_C is the partial safety factor for concrete, see 2.4.2.4, and

α_{cc} is the coefficient taking account of long term effects on the compressive strength and of unfavourable effects resulting from the way the load is applied.

> **Note:** The value of α_{cc} for use in a Country should lie between 0,80 and 1,00 and may be found in its National Annex. The recommended value of α_{cc} is 0,85.

(102)P The value of the design tensile strength, f_{ctd}, is defined as

$$f_{ctd} = \alpha_{ct} \, f_{ctk,0,05} / \gamma_C$$

where:
γ_C is the partial safety factor for concrete, see 2.4.2.4, and
α_{ct} is a coefficient taking account of long term effects on the tensile strength and of unfavourable effects, resulting from the way the load is applied.

Note: The value of α_{ct} for use in a Country should lie between 0,80 and 1,00 and may be found in its National Annex. The recommended value of α_{ct} is 1,0.

3.2 Reinforcing steel

3.2.4 Ductility characteristics

(101)P   The reinforcement shall have adequate ductility as defined by the ratio of tensile strength to the yield stress, $(f_t/f_y)_k$ and the elongation at maximum force, ε_{uk} .

Note: The classes of reinforcement to be used in bridges in a Country may be found in its National Annex. The recommended classes are Class B and Class C.

SECTION 4 DURABILITY AND COVER TO REINFORCEMENT

The following clauses of EN 1992-1-1 apply.

4.1 (1)P	*4.2 (3)*	*4.4.1.2 (4)*	*4.4.1.2 (13)*
4.1 (2)P	*4.3 (1)P*	*4.4.1.2 (5)*	*4.4.1.3 (1)P*
4.1 (3)P	*4.3 (2)P*	*4.4.1.2 (6)*	*4.4.1.3 (2)*
4.1 (4)	*4.4.1.1 (1)P*	*4.4.1.2 (7)*	*4.4.1.3 (3)*
4.1 (5)	*4.4.1.1 (2)P*	*4.4.1.2 (8)*	*4.4.1.3 (4)*
4.1 (6)	*4.4.1.2 (1)P*	*4.4.1.2 (10)*	
4.2 (1)P	*4.4.1.2 (2)P*	*4.4.1.2 (11)*	
4.2 (2)	*4.4.1.2 (3)*	*4.4.1.2 (12)*	

4.2 Environmental conditions

(104) Water penetration or the possibility of leakage from the carriageway into the inside of voided structures should be considered in design.

(105) For a concrete surface protected by waterproofing the exposure class should be given in a Country's National Annex.

Note: For surfaces protected by waterproofing the exposure class for use in a Country may be found in its National Annex. The recommended exposure class for surfaces protected by waterproofing is XC3.

(106) Where de-icing salt is used, all exposed concrete surfaces within x m of the carriageway horizontally or within y m above the carriageway should be considered as being directly affected by de-icing salts. Top surfaces of supports under expansion joints should also be considered as being directly affected by de-icing salts.

Note 1: The distances x and y for use in a Country may be found in its National Annex. The recommended value for x is 6m and the recommended value for y is 6m.

Note 2: The exposure classes for surfaces directly affected by de-icing salts for use in a Country may be found in its National Annex. The recommended classes for surfaces directly affected by de-icing salts are XD3 and XF2 or XF4, as appropriate, with covers given in Tables 4.4N and 4.5N for XD classes.

4.3 Requirements for durability

(103) External prestressing tendons should comply with the requirements of National Authorities.

4.4 Methods of verifications

4.4.1 Concrete cover

4.4.1.2 Minimum cover, c_{min}

(109) Where in-situ concrete is placed against an existing concrete surface (precast or in-situ) the requirements for cover to the reinforcement from the interface may be modified.

Note: The requirements for use in a Country may be found in its National Annex.

The recommended requirement is that, provided the following conditions are met, the cover needs only satisfy the requirements for bond (see 4.4.1.2 (3) of EN 1992-1-1):
- the existing concrete surface has not been subject to an outdoor environment for more than 28 days.
- the existing concrete surface is rough.
- the strength class of the existing concrete is at least C25/30

(114) Bare concrete decks of road bridges, without waterproofing or surfacing, should be classified as Abrasion Class XM2.

(115) Where a concrete surface is subject to abrasion caused by ice or solid transportation in running water the cover should be increased by a minimum of 10mm.

SECTION 5 STRUCTURAL ANALYSIS

The following clauses of EN 1992-1-1 apply.

5.1.1 (1)P	*5.6.1 (3)P*	*5.8.5 (2)*	*5.10.1 (3)*
5.1.1 (2)	*5.6.1 (4)*	*5.8.5 (3)*	*5.10.1 (4)*
5.1.1 (3)	*5.6.2 (1)P*	*5.8.5 (4)*	*5.10.1 (5)P*
5.1.1 (4)P	*5.6.2 (3)*	*5.8.6 (1)P*	*5.10.2.1 (1)P*
5.1.1 (5)	*5.6.2 (4)*	*5.8.6 (2)P*	*5.10.2.1 (2)*
5.1.1 (6)P	*5.6.2 (5)*	*5.8.6 (3)*	*5.10.2.2 (1)P*

5.5 (3)	*5.8.4 (3)*	*5.9 (4)*	*5.11 (1)P*
5.5 (6)	*5.8.4 (4)*	*5.10.1 (1)P*	*5.11 (2)P*
5.6.1 (2)P	*5.8.5 (1)*	*5.10.1 (2)*	

5.1 General

5.1.1 General requirements

(108) For the analysis of time dependant effects in bridges, specific design methods may be applied.

> **Note:** Further information may be found in Annex KK.

5.1.3 Load cases and combinations

(101)P In considering the combinations of actions (see Section 6 and Annex A2 of EN 1990) the relevant load cases shall be considered to enable the critical design conditions to be established at all sections, within the structure or part of the structure considered.

Note: Simplifications to the load arrangements for use in a Country may be found in its National Annex. No simplifications are recommended in this standard.

5.2 Geometric imperfections

(104) The provisions of (105) and (106) of this Part and (7) of EN 1992-1-1 apply to members with axial compression and structures with vertical load. Numerical values are related to normal execution deviations (Class 1 in EN 13670). Where other execution deviations apply numerical values should be adjusted accordingly.

(105) Imperfections may be represented by an inclination, θ_l, given by

$$\theta_l = \theta_0 \cdot \alpha_h \qquad\qquad (5.101)$$

where
θ_0 is the basic value:

α_h is the reduction factor for length or height: $\alpha_h = 2/\sqrt{l}$; $\alpha_h \leq 1$
l is the length or height [m]

Note: The value of θ_0 to use in a Country may be found in its National Annex. The recommended value is 1/200

(106) For arch bridges, the shape of imperfections in the horizontal and vertical planes should be based on the shape of the first horizontal and vertical buckling mode shape respectively. Each mode shape may be idealised by a sinusoidal profile. The amplitude should be taken as $a = \theta_l \dfrac{l}{2}$, where l is the half wavelength.

(8) and (9) of EN 1992-1-1 do not apply.

5.3 Idealisation of the structure

5.3.1 Structural models for overall analysis

(2) and (6) of EN 1992-1-1 do not apply

5.3.2 Geometric data

5.3.2.2 Effective span of beams and slabs

Note: (1), (2) and (3) of EN 1992-1-1 apply despite the fact that the title of the clause refers to buildings.

(104) Where a beam or slab is continuous over a support which may be considered to provide no restraint to rotation (e.g. over walls) and the analysis assumes point support, the design

support moment, calculated on the basis of a span equal to the centre- centre distance between supports, may be reduced by an amount ΔM_{Ed} as follows:

$$\Delta M_{Ed} = F_{Ed,sup} \, t \, / \, 8 \qquad (5.9)$$

where:

$F_{Ed,sup}$ is the design support reaction

Note: The value of t for use in a Country may be found in its National Annex. The recommended value is the breadth of the bearing.

5.5 Linear elastic analysis with limited redistribution

(104) In continuous beams or slabs which:
     a) are predominantly subject to flexure and
     b) have the ratio of the lengths of adjacent spans in the range of 0,5 to 2
redistribution of bending moments may be carried out without explicit check on the rotation capacity, provided that:

$$\delta \geq k_1 + k_2 x_u/d \quad \text{for } f_{ck} \leq 50 \text{ MPa} \qquad (5.10a)$$
$$\delta \geq k_3 + k_4 x_u/d \quad \text{for } f_{ck} > 50 \text{ MPa} \qquad (5.10b)$$
$$\delta \geq k_5 \text{ where Class B and Class C reinforcement is used (see Annex C)}$$

No redistribution is allowed for Class A steel (see Annex C)

Where:
δ is the ratio of the redistributed moment to the elastic bending moment
x_u is the depth of the neutral axis at the ultimate limit state after redistribution
d   is the effective depth of the section

Note: The values of k_1, k_2, k_3, k_4, k_5 for use in a Country may be found in its National Annex. The recommended value for k_1 is 0,44, for k_2 is $1,25(0,6+0,0014/\varepsilon_{cu2})$, for k_3 is 0,54, for k_4 is $1,25(0,6+0,0014/\varepsilon_{cu2})$ and for k_5 is 0,85.
Note: The limits of EN1992-1-1 may be used for the design of solid slabs.

(105) Redistribution should not be carried out in circumstances where the rotation capacity cannot be defined with confidence (e.g. in curved and or skewed bridges).

5.6 Plastic analysis

5.6.1 General

(101)P Where permitted by National Authorities, methods based on plastic analysis may be used for the check at ULS.

5.6.2 Plastic analysis for beams, frames and slabs

(102) The required ductility may be deemed to be satisfied if all the following are fulfilled:
     i)   the area of tensile reinforcement is limited such that, at any section
          x_u/d $\leq 0,15$ for concrete strength classes $\leq$ C50/60
            $\leq 0,10$ for concrete strength classes $\geq$ C55/67
     ii)   reinforcing steel is either Class B or C
     iii)   the ratio of the moments at intermediate supports to the moments in the span is between 0,5 and 2.

Note: The limits of EN1992-1-1 may be used for the design of solid slabs.

5.6.3 Rotation capacity

(102) In regions of yield hinges, x_u/d should not exceed 0,30 for concrete strength classes less than or equal to C50/60, and 0,23 for concrete strength classes greater than or equal to C55/67.

5.7 Non-linear analysis

(105) Non-linear analysis may be used provided that the model can appropriately cover all failure modes (e.g. bending, axial force, shear, compression failure affected by reduced effective concrete strength, etc…) and that the concrete tensile strength is not utilised as a primary load resisting mechanism.

If one analysis is not sufficient to verify all the failure mechanisms, separate additional analyses should be carried out.

Note 1: The details of acceptable methods for non-linear analysis and safety format to be used in a Country may be found in its National Annex. The recommended details are as follows:

When using non-linear analysis the following assumptions should be made:

- For reinforcing steel, the stress-strain diagram to be used should be based on Figure 3.8, curve A. In this diagram, f_{yk} and kf_{yk} should be replaced by $1,1f_{yk}$ and $1,1kf_{yk}$

- For prestressing steel, the idealised stress-strain diagram given in 3.3.6 (Figure 3.10, curve A) should be used. In this diagram f_{pk} should be replaced with $1.1 f_{pk}$

- For concrete, the stress-strain diagram should be based on expression (3.14) in 3.1.5. In this expression, and in the k-value, f_{cm} should be replaced by $\gamma_{cf} . \alpha_{cc} . f_{ck}$ with $\gamma_{cf} . \alpha_{cc} = 1,1. \gamma_S / \gamma_C$

The following design format should be used:

- The resistance should be evaluated for different levels of appropriate actions which should be increased from their serviceability values by incremental steps, such that the value of $\gamma_G . G_k$ and $\gamma_Q . Q_k$ are reached in the same step. The incrementing process should be continued until one region of the structure attains the ultimate strength or there is global failure of the structure. The corresponding load is referred to as q_{ud} .

- Apply an overall safety factor γ_O and obtain the corresponding strength $R\left(\dfrac{q_{ud}}{\gamma_O}\right)$,

- If one of the following inequalities is satisfied, the structure is deemed to be safe :

$$\gamma_{Rd}E(\gamma_G G + \gamma_Q Q) \le R\left(\frac{q_{ud}}{\gamma_O}\right) \qquad \text{(5.102 aN)}$$

or

$$E(\gamma_G G + \gamma_Q Q) \le R\left(\frac{q_{ud}}{\gamma_{Rd} . \gamma_O}\right) \qquad \text{(5.102 bN)}$$

$$\text{(i.e.)} \quad R\left(\frac{q_{ud}}{\gamma_{O'}}\right)$$

or

$$\gamma_{Rd}\gamma_{Sd}E\left(\gamma_g G + \gamma_q Q\right) \le R\left(\frac{q_{ud}}{\gamma_O}\right) \qquad (5.102\ cN)$$

Where :

γ_{Rd} is the partial factor for model uncertainty for resistance, γ_{Rd} = 1,06 ,

γ_{Sd} is the partial factor for model uncertainty for action / action effort, γ_{Sd}= 1,15 ,

γ_O is the overall safety factor, γ_O = 1,20 .

Refer to Annex PP for further details.

When model uncertainties γ_{Rd} and γ_{Sd} are not considered explicitly in the analysis (i.e. γ_{Rd} = γ_{Sd} = 1), $\gamma_{O'}$ = 1,27 should be used.

Note 2: If design properties of materials (e.g. as 5.8.6 of EN 1992-1-1) are used for non-linear analysis particular care should be exercised to allow for the effects of indirect actions (e.g. imposed deformations).

5.8 Second order effects with axial load

5.8.3 3 Global second order effects in buildings

This clause does not apply

5.8.4 Creep

(105) A more refined approach to the evaluation of creep may be applied.

> **Note:** Further information may be found in Annex KK

5.10 Prestressed members and structures

5.10.1 General

(106) Brittle failure should be avoided using the method described in 6.1 (109).

5.10.8 Effects of prestressing at ultimate limit state

(103) If the stress increase in external tendons is calculated using the deformation state of the overall member non-linear analysis should be used. See 5.7.

SECTION 6 ULTIMATE LIMIT STATES (ULS)

The following clauses of EN 1992-1-1 apply.

6.1 (1)P	*6.2.4 (6)*	*6.4.3 (1)P*	*6.5.4 (9)*
6.1 (2)P	*6.2.4 (7)*	*6.4.3 (2)*	*6.6 (1)P*
6.1 (3)P	*6.2.5 (1)*	*6.4.3 (3)*	*6.6 (2)*

6.2.4 (2)	*6.4.2 (10)*	*6.5.4 (7)*	
6.2.4 (4)	*6.4.2 (11)*	*6.5.4 (8)*	

6.1 Bending with or without axial force

(108) For external prestressing tendons the strain in the prestressing steel between two consecutive fixed points is assumed to be constant. The strain in the prestressing steel is then equal to the remaining strain, after losses, increased by the strain resulting from the structural deformation between the fixed points considered.

(109) For prestressed structures, 5(P) of 5.10.1 may be satisfied by any of the following methods:

   a) Verifying the load capacity using a reduced area of prestress. This verification should be undertaken as follows:
   i. Calculate the applied bending moment due to the frequent combination of actions.
   ii. Determine the reduced area of prestress that results in the tensile stress reaching f_{ctm} at the extreme tension fibre when the section is subject to the bending moment calculated in i. above.

    iii.   Using this reduced area of prestress, calculate the ultimate flexural capacity. It should be ensured that this exceeds the bending moment due to the frequent combination. Redistribution of internal actions within the structure may be taken into account for this verification and the ultimate bending resistance should be calculated using the material partial safety factors for accidental design situations given in Table 2.1N of 2.4.2.4.

  b) Providing a minimum reinforcing steel area according to the Expression (6.101a). Reinforcing steel provided for other purposes may be included in $A_{s,min}$.

$$A_{s,min} = \frac{M_{rep}}{z_s f_{yk}}$$
(6.101a)

where:
M_{rep} is the cracking bending moment calculated assuming a tensile stress equal to f_{ctm} at the extreme tension fibre of the section, ignoring any effect of prestressing. At the joint of segmental precast elements M_{rep} should be assumed to be zero.
z_s is the lever arm at the ultimate limit state related to the reinforcing steel.

  c) Providing satisfactory evidence concerning the reliability of the tendons by means of monitoring or by proven external inspection techniques.

(110) In cases where method b) in (109) above is chosen, the following rules apply:

  i.   The minimum reinforcement steel area should be provided in regions where tensile stresses occur in the concrete under the characteristic combination of actions. In this check the parasitic effects of prestressing should be considered, the primary effects should be ignored.

  ii.   For pretensioned members Expression (6.101a) should be applied using one of the alternative approaches a) or b) described below:
a)   tendons with concrete cover at least k_{cm} times the minimum specified in 4.4.1.2 are considered as effective in $A_{s,min}$. A value of z_s based on the effective strands is used in the expression and f_{yk} is replaced with $f_{p0,1k}$.
b)   tendons subject to stresses lower than $0{,}6 f_{pk}$ after losses under the characteristic combination of actions are considered as fully active. In this case Expression (6.101a) is replaced by :

$$A_{s,min} f_{yk} + A_p \Delta\sigma_p \geq \frac{M_{rep}}{z}$$
(6.101b)

where $\Delta\sigma_p$ is the smaller of $0{,}4 f_{ptk}$ and 500 Mpa.

Note : The value of k_{cm} for use in a Country may be found in its National Annex. The recommended value for k_{cm} is 2,0.

  iii. To ensure adequate ductility the minimum reinforcing steel area $A_{s,min}$, defined in Expressions (6.101), in continuous beams should extend to the intermediate support of the span considered.
However, this extension is not necessary if, at the ultimate limit state, the resisting tensile capacity provided by reinforcing and prestressing steel above the supports, calculated

with the characteristic strength f_{yk} and $f_{p0,1k}$ respectively, is less than the resisting compressive capacity of the bottom flange, which means that the failure of the compressive zone is not likely to occur:

$$A_s f_{yk} + k_p A_p f_{p0,1k} < t_{inf} b_0 \alpha_{cc} f_{ck} \tag{6.102}$$

where:

t_{inf} , b_0 are, respectively, the thickness and the width of the bottom flange of the section. In the case of T sections, t_{inf} is taken as equal to b_0.

A_s , A_p denote respectively the area of ordinary and prestressing steel in the tensile zone at the ultimate limit state.

Note : The value of k_p for use in a Country may be found in it's National Annex. The recommended value for k_p is 1,0.

6.2 Shear

6.2.2 Members not requiring design shear reinforcement

(101) The design value for the shear resistance $V_{Rd,c}$ is given by:

$$V_{Rd,c} = [C_{Rd,c}k(100\, \rho_l\, f_{ck})^{1/3} + k_1\, \sigma_{cp}]\, b_w d \tag{6.2.a}$$

with a minimum of

$$V_{Rd,c} = (v_{min} + k_1\sigma_{cp})\, b_w d \tag{6.2.b}$$

where:
f_{ck} is in MPa

$k \quad = 1 + \sqrt{\dfrac{200}{d}} \le 2,0$ with d in mm

$\rho_l \quad = \dfrac{A_{sl}}{b_w d} \le 0,02$

A_{sl} area of the tensile reinforcement, which extends $\ge$ (l_{bd} + d) beyond the section considered (see Figure 6.3); the area of bonded prestressing steel may be included in the calculation of A_{sl}. In this case a weighted mean value of d may be used.

b_w is the smallest width of the cross-section in the tensile area [mm]

$\sigma_{cp} = N_{Ed}/A_c < 0,2\, f_{cd}$ [MPa]

N_{Ed} axial force in the cross-section due to loading or to the acting effect of prestressing in Newtons ($N_{Ed} > 0$ for compression). The influence of imposed deformations on N_{Ed} may be ignored.

A_C is the area of concrete cross section [mm^2]

$V_{Rd,c}$ is [N]

Note: The values of $C_{Rd,c}$, v_{min} and k_1 for use in a Country may be found in its National Annex. The recommended value for $C_{Rd,c}$ is 0,18/γ_c, that for v_{min} is given by Expression (6.3N) and that for k_1 is 0,15.

$$v_{min} = 0,035\, k^{3/2} \cdot f_{ck}^{1/2} \tag{6.3N}$$
$\boxed{A}$ - section considered

Figure 6.3: Definition of A_{sl} in Expression (6.2)

6.2.3 Members requiring design shear reinforcement

(103) For members with vertical shear reinforcement, the shear resistance, V_{Rd} is the smaller value of:

$$V_{Rd,s} = \frac{A_{sw}}{s} z\, f_{ywd} \cot\theta \tag{6.8}$$

Note: If Expression (6.10) is used the value of f_{ywd} should be reduced to $0{,}8\, f_{ywk}$ in Expression (6.8)

and

$$V_{Rd,max} = \alpha_{cw}\, b_w\, z\, \nu_1\, f_{cd}/(\cot\theta + \tan\theta) \tag{6.9}$$

where:
A_{sw} is the cross-sectional area of the shear reinforcement
s is the spacing of the stirrups
f_{ywd} is the design yield strength of the shear reinforcement
ν_1 is a strength reduction factor for concrete cracked in shear
α_{cw} is a coefficient taking account of the interaction of the stress in the compression chord and any applied axial compressive stress

Note: The value of ν_1 and α_{cw} for use in a Country may be found in its National Annex. The recommended value of ν_1 is ν.

For reinforced and prestressed members, if the design stress of the shear reinforcement is below 80% of the characteristic yield stress f_{yk}, ν_1 may be taken as:
ν_1 = 0,6   for $f_{ck} \leq 60$ MPa   (6.10.aN)
ν_1 = 0,9 – f_{ck} /200 > 0,5   for $f_{ck} \geq 60$ MPa   (6.10.bN)

The recommended value of α_{cw} is as follows:
1 for non-prestressed structures
(1 + σ_{cp}/f_{cd})   for $0 < \sigma_{cp} \leq 0{,}25\, f_{cd}$ (6.11.aN)
1,25   for $0{,}25\, f_{cd} < \sigma_{cp} \leq 0{,}5\, f_{cd}$ (6.11.bN)
2,5 (1 - σ_{cp}/f_{cd})   for $0{,}5\, f_{cd} < \sigma_{cp} < 1{,}0\, f_{cd}$ (6.11.cN)
where:
σ_{cp} is the mean compressive stress, measured positive, in the concrete due to the design axial force. This should be obtained by averaging it over the concrete section taking account of the reinforcement. The value of σ_{cp} need not be calculated at a distance less than $0.5d \cot\theta$ from the edge of the support.

In the case of straight tendons, a high level of prestress ($\sigma_{cp}/f_{cd} > 0,5$) and thin webs, if the tension and the compression chords are able to carry the whole prestressing force and blocks are provided at the extremity of beams to disperse the prestressing force (see fig. 6.101), it may be assumed that the prestressing force is distributed between the chords. In these circumstances, the compression field due to shear only should be considered in the web ($\alpha_{cw}=1$).

Figure 6.101: Dispersion of prestressing by end blocks within the chords.

The maximum effective cross-sectional area of the shear reinforcement $A_{sw,max}$ is given by:

$$\frac{A_{sw,max} f_{ywd}}{b_w s} \leq \tfrac{1}{2} \alpha_{cw} \nu_1 f_{cd} \tag{6.12}$$

(107) The additional tensile force, ΔF_{td}, in the longitudinal reinforcement due to shear V_{Ed} may be calculated from:

$$\Delta F_{td} = 0,5\ V_{Ed} (\cot \theta - \cot \alpha) \tag{6.18}$$

(M_{Ed}/z) + ΔF_{td} should be taken not greater than $M_{Ed,max}/z$.

Note : Guidance on the superposition of different truss models for use in a Country may be found in its National Annex . The recommended guidance is as follows :
In the case of bonded prestressing, located within the tensile chord, the resisting effect of prestressing may be taken into account for carrying the total longitudinal tensile force. In the case of inclined bonded prestressing tendons in combination with other longitudinal reinforcement/tendons the shear strength may be evaluated, by a simplification, superimposing two different truss models with different geometry (fig. 6.102N); a weighted mean value between θ_1 and θ_2 may be used for concrete stress field verification with Expression (6.9).

Figure 6.102N: Superimposed resisting model for shear

(109) In the case of segmental construction with precast elements and no bonded prestressing in the tension chord, the effect of opening of the joint should be considered. In these conditions, in the absence of a detailed analysis, the force in the tension chord should be

assumed to remain unchanged after the joints have opened. In consequence, as the applied load increases and the joints open (Figure 6.103), the concrete stress field inclination within the web increases. The depth of concrete section available for the flow of the web compression field decreases to a value of h_{red}. The shear capacity can be evaluated in accordance with Expression 6.8 by assuming a value of θ derived from the minimum value of residual depth h_{red}.
Field A : arrangement of stirrups with θ_{max} (cot θ = 1.0)
Field B : arrangement of stirrups with θ_{min} (cot θ = 2.5)

Figure 6.103: Diagonal stress fields across the joint in the web

$$h_{red} = \frac{V_{Ed}}{b_w\, \nu\, f_{cd}}\left(\cot\theta + \tan\theta\right)$$ (6.103)

Shear reinforcement stirrups, having the following area per unit length:

$$\frac{A_{sw}}{s} = \frac{V_{Ed}}{h_{red} f_{ywd}\, \cot\theta}$$ (6.104)

should be provided within a distance $h_{red}\cot\theta$, but not greater than the segment length, from both edges of the joint.

The prestressing force should be increased if necessary such that, at the ultimate limit state, under the combination of bending moment and shear, the joint opening is limited to the value $h - h_{red}$ as calculated above.

> **Note :** The absolute minimum value of h_{red} to be used in a Country may be found in its National Annex. The recommended absolute minimum value for h_{red} is 0.5h.

6.2.4 Shear between web and flanges of T-sections

(103) The longitudinal shear stress, $v_{Ed,}$ at the junction between one side of a flange and the web is determined by the change of the normal (longitudinal) force in the part of the flange considered, according to:

$$v_{Ed} = \Delta F_d/(h_f \cdot \Delta x) \tag{6.20}$$

where:

h_f is the thickness of flange at the junctions

Δx is the length under consideration, see Figure 6.7

ΔF_d is the change of the normal force in the flange over the length Δx.

A - compressive struts B - longitudinal bar anchored beyond this projected point (see 6.2.4 (7))
Figure 6.7:   Notations for the connection between flange and web

The maximum value that may be assumed for Δx is half the distance between the section where the moment is 0 and the section where the moment is maximum. Where point loads are applied the length Δx should not exceed the distance between point loads.

Alternatively, considering a length Δx of the beam, the shear transmitted from the web to the flange is $V_{Ed}\Delta x$ /z and is divided into three parts: one remaining within the web breadth and the other two going out to the flange outstands ($\Delta Fd+\Delta Fd$). It should be generally assumed that the proportion of the force remaining within the web is the fraction b_w/b_f of the total force. A greater proportion may be assumed if the full effective flange breadth is not required to resist the bending moment. In this case a check for cracks opening at SLS may be necessary.

(105) In the case of combined shear between the flange and the web, and transverse bending, the area of steel should be the greater of that given by Expression (6.21) or half that given by Expression (6.21) plus that required for transverse bending.

For the verification of concrete compression crushing according to Expression (6.22) of EN 1992-1-1 h_f should be reduced by the depth of compression considered in the bending assessment. If this verification is not satisfied the refined method given in Annex MM may be used.

6.2.5 Shear at the interface between concrete cast at different times

(105) Under fatigue or dynamic loads, the values for c in 6.2.5 (1) in EN1992-1-1 should be taken as zero.

6.2.106 Shear and transverse bending

(101) Due to the presence of compressive stress fields arising from shear and bending, the interaction between longitudinal shear and transverse bending in the webs of box girder sections should be considered in the design.

When $V_{Ed}/V_{Rd,max}$<0,2 or $M_{Ed}/M_{Rd,max}$<0,1 this interaction can be disregarded; where $V_{Rd,max}$ and $M_{Rd,max}$ represent respectively the maximum web capacity for longitudinal shear and transverse bending.

> **Note:** Further information on the interaction between shear and transverse bending may be found in Annex MM.

6.3 Torsion

6.3.2 Design procedure

(102) The required transverse reinforcement for the effects of torsion and shear for both hollow and solid members may be superimposed, assuming the same value for the strut inclination θ. The limits for θ given in 6.2.3 (2) are also fully applicable for the case of combined shear and torsion.

The maximum bearing capacity of a member loaded in shear and torsion follows from 6.3.2 (4).

For box sections, each wall may be calculated separately, for the combination of shear forces derived from shear and torsion (fig 6.104).

| Torsion | Shear | Combination |

Figure 6.104: Internal actions combination within the different walls of a box section.

(103) The required area of the longitudinal reinforcement for torsion ΣA_{sl} may be calculated from Expression (6.28):

$$\frac{\Sigma A_{sl} f_{yd}}{u_k} = \frac{T_{Ed}}{2A_k} \cot\theta \qquad (6.28)$$

where
u_k is the perimeter of the area A_k

f_{yd} is the design yield stress of the longitudinal reinforcement A_{sl}

θ is the angle of compression struts (see Figure 6.5).

In compressive chords, the longitudinal reinforcement may be reduced in proportion to the available compressive force. In tensile chords the longitudinal reinforcement for torsion should be added to the other reinforcement. The longitudinal reinforcement should generally be distributed over the length of side, z_i, but for smaller sections it may be concentrated at the ends of this length.

Bonded prestressing tendons can be taken into account limiting their stress increase to $\Delta\sigma_p \leq 500$ MPa. In that case, $\sum A_{sl} f_{yd}$ in Expression (6.28) is replaced by $\sum A_{sl} f_{yd} + A_p \Delta\sigma_p$.

(104) The maximum resistance of a member subjected to torsion and shear is limited by the capacity of the concrete struts. In order not to exceed this resistance the following condition should be satisfied:

-     for solid cross-sections:

$$T_{Ed} / T_{Rd,max} + V_{Ed} / V_{Rd,max} \leq 1,0 \tag{6.29}$$

where:

T_{Ed} is the design torsional moment

V_{Ed} is the design transverse force

$T_{Rd,max}$ is the design torsional resistance moment according to

$$T_{Rd,max} = 2\nu\,\alpha_{cw}\,f_{cd}\,A_k\,t_{ef,i}\,\sin\theta\,\cos\theta \tag{6.30}$$

      where ν follows from Expression (6.6) and α_c from Expression (6.9)

$V_{Rd,max}$ is the maximum design shear resistance according to Expressions (6.9) or (6.14). In solid cross sections the full width of the web may be used to determine $V_{Rd,max}$

In box sections, where each wall is designed separately for combined effects of shear and torsion, the ultimate limit state for concrete should be checked with reference to the design shear resistance $V_{Rd,max}$.

(106) In the case of segmental construction with precast box elements and no internal bonded prestressing in the tension region, the opening of a joint to an extension greater than the thickness of the corresponding flange entails a substantial modification of the torsional resisting mechanism if the relevant shear keys are not able to transfer the local shear due to torsion. It changes from Bredt circulatory torsion to a combination of warping torsion and De Saint Venant torsion, with the first mechanism prevailing over the second (fig. 6.105). As a consequence, the web shear due to torsion is practically doubled and significant distortion of the section takes place. In these circumstances, the capacity at the ultimate limit state should be verified in the most heavily stressed web according to the procedure in Annex MM taking into account the combination of bending, shear and torsion.
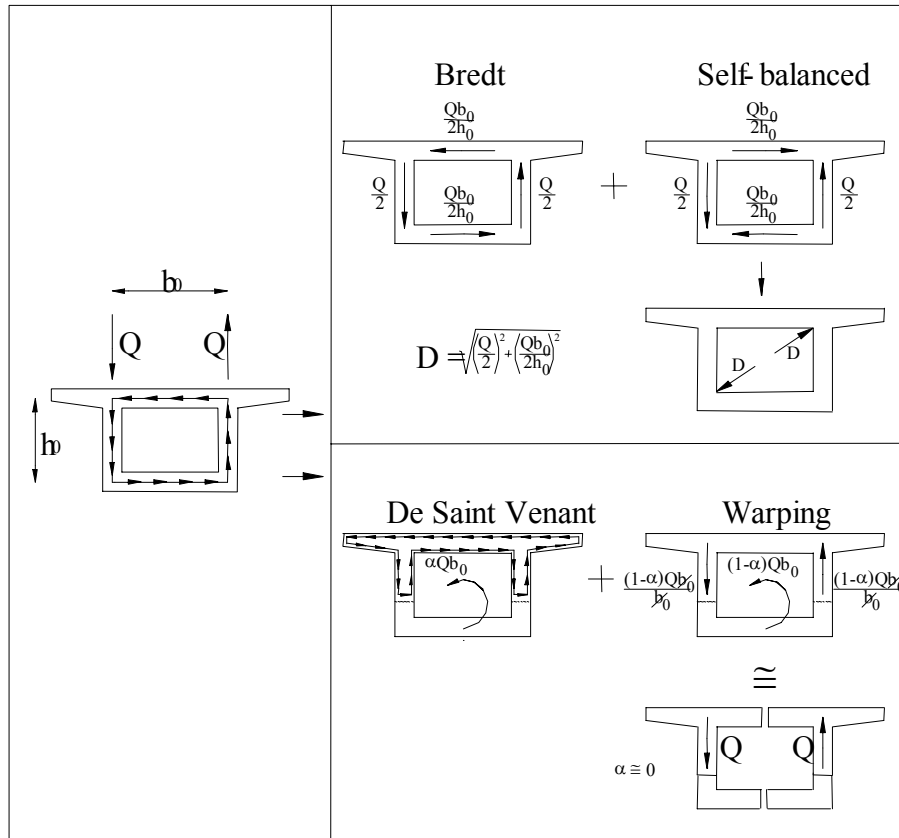

Figure 6.105: Variation in torsional behaviour from closed to opened joint.

6.7 Partially loaded areas

(105) The design of bearing zones for bridges should be carried out using recognised methods.

> **Note:** Further information may be found in Annex J

6.8 Fatigue

6.8.1 Verification conditions

(102) A fatigue verification should be carried out for structures and structural components which are subjected to regular load cycles.

> **Note:** A fatigue verification is generally not necessary for the following structures and structural elements:
>   a) footbridges, with the exception of structural components very sensitive to wind action;
>   b) buried arch and frame structures with a minimum earth cover of 1.00 m and 1.50 m respectively for road and railway bridges;
>   c) foundations;
>   d) piers and columns which are not rigidly connected to superstructures
>   e) retaining walls of embankments for roads and railways
>   f) abutments of road and railway bridges which are not rigidly connected to superstructures, except the slabs of hollow abutments;
>   g) prestressing and reinforcing steel, in regions where, under the frequent combination of actions and $P_{k,}$, only compressive stresses occur at the extreme concrete fibers;
>   The National Annex may define additional rules.

6.8.4 Verification procedure for reinforcing and prestressing steel

(107) Fatigue verification for external and unbonded tendons, lying within the depth of the concrete section, is not necessary.

6.8.7 Verification of concrete under compression

(101) The verification should be carried out using traffic data, S-N curves and load models specified by the National Authorities. A simplified approach based on λ values may be used for the verification; see Annex NN.

Miner's rule should be applied for the verification of concrete; accordingly $\sum_{i=1}^{m} \dfrac{n_i}{N_i} \leq 1$ where:

- m = number of intervals with constant amplitude
- n_i = actual number of constant amplitude cycles in interval "i"
- Ni = ultimate number of constant amplitude cycles in interval "i" that can be carried before failure. Ni may be given by National Authorities (S-N curves) or calculated on a simplified basis using expression 6.72 of EN 1992-1-1 substituting the coefficient 0,43 with $(\log N_i)/14$ and transforming the inequality in the expression.

Then a satisfactory fatigue resistance may be assumed for concrete under compression, if the following condition is fulfilled:

$$\sum_{i=1}^{m} \frac{n_i}{N_i} \left(E_{cd,max,i} + \frac{\log N_i}{14} \sqrt{1 - R_i} \right) \leq 1 \tag{6.106}$$

where:

$$R_i = \frac{E_{cd,min,i}}{E_{cd,max,i}} \tag{6.107}$$

$$E_{cd,min,i} = \frac{\sigma_{cd,min,i}}{f_{cd,fat}} \tag{6.108}$$

$$E_{cd,max,i} = \frac{\sigma_{cd,max,i}}{f_{cd,fat}} \tag{6.109}$$

where :

R_i	is the stress ratio
$E_{cd,min,i}$	is the minimum compressive stress level
$E_{cd,max,i}$	is the maximum compressive stress level
$f_{cd,fat}$	is the design fatigue strength of concrete according to (6.76)
$\sigma_{cd,max,i}$	is the upper stress in a cycle
$\sigma_{cd,min,i}$	is the lower stress in a cycle

$$f_{cd,fat} = k_1 \beta_{cc}(t_0) f_{cd} \left(1 - \frac{f_{ck}}{250} \right) \tag{6.76}$$

where:

$\beta_{cc}(t_0)$ is a coefficient for concrete strength at first load application (see 3.1.2 (6) of EN 1992-1-1)

t_0 is the time of the start of the cyclic loading on concrete in days

Note: The value of k_1 for use in a Country may be found in its National Annex. The recommended value is 0,85.

Note: See also Annex NN for further information.

6.109 Membrane elements

(101) Membrane elements may be used for the design of two-dimensional concrete elements subject to a combination of internal forces evaluated by means of a linear finite element analysis. Membrane elements are subjected only to in plane forces, namely σ_{Edx}, σ_{Edy}, τ_{Edxy} as shown in Figure 6.106
Figure 6.106: Membrane element

(102) Membrane elements may be designed by application of the theory of plasticity using a lower bound solution.

(103) The maximum value for compressive stress field strength should be defined as a function of the principal stress values:

i) If the principal stresses are both compressive, the maximum compression in the concrete stress field is:

$$\sigma_{cd\,max} = 0.85 f_{cd} \frac{1 + 3,80\alpha}{(1+\alpha)^2} \tag{6.110}$$

where $\alpha \leq 1$ is the ratio between the two principal stresses.

ii) Where a plastic analysis has been carried out with $\theta = \theta_{el}$ and at least one principal stress is in tension and no reinforcement yields, the maximum compression in the concrete stress field is given by:

$$\sigma_{cd\,max} = f_{cd}\left[0,85 - \frac{\sigma_s}{f_{yd}}(0,85 - v)\right] \tag{6.111}$$

where σ_s is the maximum tensile stress in the reinforcement, and v is defined in 6.2.2 (6) of EN 1992-1-1.

iii) Where a plastic analysis has been carried out and there is yielding of any reinforcement, the maximum compression in the concrete stress field is:

$$\sigma_{cd\,max} = v\,f_{cd}\left(1 - 0,032|\theta - \theta_{el}|\right) \tag{6.112}$$

where:

θ_{el} (in degrees) is the inclination to the x axis of the principal compression stress in the elastic analysis.

θ (in degrees) is the angle of the plastic compression field at ULS, to the x axis.

In Expression (6.112) $|\theta - \theta_{el}|$ should be limited to 15 degrees.

SECTION 7 SERVICEABILITY LIMIT STATES (SLS)

The following clauses of EN 1992-1-1 apply.

7.1 (1)P	*7.3.1 (6)*	*7.3.4 (2)*	*7.4.2 (1)P*
7.1 (2)	*7.3.1 (7)*	*7.3.4 (3)*	*7.4.2 (2)*
7.2 (1)P	*7.3.1 (8)*	*7.3.4 (4)*	*7.4.3 (1)P*
7.2 (3)	*7.3.1 (9)*	*7.3.4 (5)*	*7.4.3 (2)P*
7.2 (4)P	*7.3.2 (1)P*	*7.4.1 (1)P*	*7.4.3 (3)*
7.2 (5)	*7.3.2 (3)*	*7.4.1 (2)*	*7.4.3 (4)*
7.3.1 (1)P	*7.3.2 (4)*	*7.4.1 (3)*	*7.4.3 (5)*
7.3.1 (2)P	*7.3.3 (2)*	*7.4.1 (4)*	*7.4.3 (6)*
7.3.1 (3)	*7.3.3 (3)*	*7.4.1 (5)*	*7.4.3 (7)*
7.3.1 (4)	*7.3.3 (4)*	*7.4.1 (6)*	

7.2 Stresses

(102) Longitudinal cracks may occur if the stress level under the characteristic combination of loads exceeds a critical value. Such cracking may lead to a reduction of durability. In the absence of other measures, such as an increase in the cover to reinforcement in the compressive zone or confinement by transverse reinforcement, it may be appropriate to limit the compressive stress to a value $k_1 f_{ck}$ in areas exposed to environments of exposure classes XD, XF and XS (see Table 4.1 of EN1992-1-1).

> **Note:** The value of k_1 for use in a Country may be found in its National Annex. The recommended value is 0,6. The maximum increase in the stress limit above $k_1 fck$ in the presence of confinement may also be found in a country's National Annex. The recommended maximum increase is 10%.

7.3   Crack control

7.3.1 General considerations

(105) A limiting calculated crack width w_{max}, taking account of the proposed function and nature of the structure and the costs of limiting cracking, should be established. Due to the random nature of cracking phenomenon, actual crack widths cannot be predicted. However, if the crack widths calculated in accordance with the models given in this Standard are limited to the values given in Table 7.101N, the performance of the structure is unlikely to be impaired.

> **Note:** The value of w_{max} and the definition of decompression and its application for use in a country may be found in its National Annex. The recommended value for w_{max} and the application of the decompression limit are given in Table 7.101N. The recommended definition of decompression is noted in the text under the Table.

Table 7.101N Recommended values of w_{max} and relevant combinations rules

Exposure Class	Reinforced members and prestressed members with unbonded tendons	Prestressed members with bonded tendons
	Quasi-permanent load combination	Frequent load combination
X0, XC1	0,3[1]	0,2

XC2, XC3, XC4	0,3	$0,2^2$
XD1, XD2, XD3 XS1, XS2, XS3		Decompression
Note 1: For X0, XC1 exposure classes, crack width has no influence on durability and this limit is set to guarantee acceptable appearance. In the absence of appearance conditions this limit may be relaxed.		
Note 2: For these exposure classes, in addition, decompression should be checked under the quasi-permanent combination of loads.		

The decompression limit requires that all concrete within a certain distance of bonded tendons or their ducts should remain in compression under the specified loading.

Note: The value of the distance considered to be used in a Country may be found in its National Annex. The recommended value is 100mm.

(9) of EN 1992-1-1 does not apply

(110) In some cases it may be necessary to check and control shear cracking in webs.

Note: Further information may be found in Annex QQ.

7.3.2 Minimum reinforcement areas

(102) Unless a more rigorous calculation shows lesser areas to be adequate, the required minimum areas of reinforcement may be calculated as follows. In profiled cross sections like T-beams and box girders, minimum reinforcement should be determined for the individual parts of the section (webs, flanges).

$$A_{s,min}\sigma_s = k_c\, k\, f_{ct,eff}\, A_{ct} \qquad\qquad (7.1)$$

where:
$A_{s,min}$ is the minimum area of reinforcing steel within the tensile zone
A_{ct} is the area of concrete within tensile zone. The tensile zone is that part of the section which is calculated to be in tension just before formation of the first crack

In flanged cross sections such as T-beams and box girders the division into parts should be as indicated in Figure 7.101".

**Stress distribution for plain bending :**

Cross-sectional stresses

Figure 7.101: Example for a division of a flanged cross-section for analysis of cracking

σ_s is the absolute value of the maximum stress permitted in the reinforcement immediately after formation of the crack. This may be taken as the yield strength of the reinforcement, f_{yk}. A lower value may, however, be needed to satisfy the crack width limits according to the maximum bar size (Table 7.2) or the maximum bar spacing (Table 7.3)

$f_{ct,eff}$ is the mean value of the tensile strength of the concrete effective at the time when the cracks may first be expected to occur:

$f_{ct,eff} = f_{ctm}$ or lower, ($f_{ctm}(t)$), if cracking is expected earlier than 28 days

k is the coefficient which allows for the effect of non-uniform self-equilibrating stresses, which lead to a reduction of restraint forces

= 1,0 for webs with $h \leq 300$ mm or flanges with widths less than 300 mm

= 0,65 for webs with $h \geq 800$ mm or flanges with widths greater than 800 mm intermediate values may be interpolated

k_c is a coefficient which takes account of the stress distribution within the section immediately prior to cracking and of the change of the lever arm:

For pure tension $k_c = 1,0$

For bending or bending combined with axial forces:

- For rectangular sections and webs of box sections and T-sections:

$$k_c = 0,4 \cdot \left[1 - \frac{\sigma_c}{k_1(h/h^*)f_{ct,eff}}\right] \leq 1 \qquad (7.2)$$

- For flanges of box sections and T-sections:

$$k_c = 0,9\frac{F_{cr}}{A_{ct}f_{ct,eff}} \geq 0,5 \qquad (7.3)$$

where

σ_c is the mean stress of the concrete acting on the part of the section under consideration:

$$\sigma_c = \frac{N_{Ed}}{bh} \qquad (7.4)$$

N_{Ed} is the axial force at the serviceability limit state acting on the part of the cross-section under consideration (compressive force positive). N_{Ed} should be determined considering the characteristic values of prestress and axial forces under the relevant combination of actions

h^* $h^* = h$ for $h < 1{,}0$ m
        $h^* = 1{,}0$ m   for $h \geq 1{,}0$ m

k_1 is a coefficient considering the effects of axial forces on the stress distribution:
        $k_1 = 1{,}5$ if N_{Ed} is a compressive force

        $k_1 = \dfrac{2h^*}{3h}$ if N_{Ed} is a tensile force

- For flanges of box sections and T-sections:

$$k_c = 0{,}9 \frac{F_{cr}}{A_{ct}f_{ct,eff}} \geq 0{,}5$$
$$(7.3)$$

F_{cr} is the absolute value of the tensile force within the flange immediately prior to cracking due to the cracking moment calculated with $f_{ct,eff}$

(105) For bridges, in calculating the minimum reinforcement to cater for shrinkage, $f_{ct,eff}$ in Expression (7.1) of EN1992-1-1 should be taken as the greater of 2,9 MPa or $f_{ctm}(t)$.

7.3.3 Control of cracking without direct calculation

(101) The control of cracking without direct calculation may be performed by means of simplified methods.

Note: Details of a simplified method for control of cracking without calculation may be found in a Country's National Annex. The recommended method is given in EN 1992-1–1 7.3.3 (2) to (4).

7.3.4 Calculation of crack widths

(101) The evaluation of crack width may be performed using recognised methods.

Note: Details of recognised methods for crack width control may be found in a Country's National Annex. The recommended method is that in EN 1992- –1 7.3.4.

SECTION 8 DETAILING OF REINFORCEMENT AND PRESTRESSING TENDONS – GENERAL

The following clauses of EN 1992-1-1 apply.

8.4.4 (1)	*8.7.5.1 (6)*	*8.10.1.3 (3)*	
8.4.4 (2)	*8.7.5.1 (7)*	*8.10.2.1 (1)*	

8.9 Bundled bars

8.9.1 General

(101) Unless otherwise stated, the rules for individual bars also apply for bundles of bars. In a bundle, all the bars should be of the same characteristics (type and grade). Bars of different sizes may be bundled provided that the ratio of diameters does not exceed 1,7.

> **Note:** Details of restrictions on the use of bundled bars for use in a Country may be found in its National Annex. No additional restrictions are recommended in this standard.

8.10 Prestressing tendons

8.10.3 Anchorage zones of post-tensioned members

(104) Tensile forces due to concentrated forces should be assessed by a strut and tie model, or other appropriate representation (see 6.5). Reinforcement should be detailed assuming that it acts at its design strength. If the stress in this reinforcement is limited to 250 MPa no check of crackwidths is necessary.

(106) Particular consideration should be given to the design of anchorage zones where two or more tendons are anchored.

> **Note:** Further information may be found in Annex J

8.10.4 Anchorages and couplers for prestressing tendons

(105) The placing of couplers on more than 50% of the tendons at one cross-section should be avoided unless:

- continuous minimum reinforcement according to expression 7.1 of EN 1992-1-1 (Section 7.3.2) is provided, or

- there is a minimum residual compressive stress of 3 MPa at the cross section under the characteristic combination of actions.

> **Note:** The maximum percentage of tendons to be coupled at a section in a Country may be found in its National Annex. The recommended value is 67%.

Where a proportion of tendons are joined with couplers at a particular cross section, remaining tendons may not be joined with couplers within distance 'a' of the that cross section.

> **Note:** The distance "a" to be used in a Country may be found in its National Annex. The recommended value of a is given in Table 8.101N.

Table 8.101N: Minimum distance between sections at which tendons are joined with couplers

construction depth h	Distance a
$\leq$ 1,5 m	1,5 m
1,5 m < h < 3,0 m	a=h
$\geq$ 3,0 m	3,0 m

(106) If slabs are transversely prestressed, special consideration should be given to the arrangement of prestressing, to achieve a reasonably uniform distribution of prestress.

(107) In an aggressive environment openings and pockets which are necessary to apply the prestress to the tendons should be avoided on the upper side of carriageway slabs. Where, in exceptional circumstances, openings and pockets are provided on the upper side of carriageway slabs appropriate precautions should be taken to ensure durability.

> **Note:** Additional rules relating to the provision of openings and pockets on the upper side of carriageway slabs for use in a Country may be found in its National Annex. No additional rules are recommended in this standard.

(108) If tendons are anchored at a construction joint or within a concrete member (whether on an external rib, within a pocket or entirely inside the member), it should be checked that a minimum residual compressive stress of at least 3 MPa is present in the direction of the anchored prestressing force, under the frequent load combination. If the minimum residual stress is not present, reinforcement should be provided to cater for the local tension behind the anchor. The check for residual stress is not required if the tendon is coupled at the anchorage considered.

SECTION 9 DETAILING OF MEMBERS AND PARTICULAR RULES

The following clauses of EN 1992-1-1 apply.

9.1 (1)P	*9.2.3 (1)*	*9.4.2 (1)*	*9.8.1 (1)*
9.1 (2)	*9.2.3 (2)*	*9.4.3 (1)*	*9.8.1 (2)*

9.2.2 (8)	*9.4.1 (3)*	*9.7 (3)*	

9.1 General

(103) Minimum areas of reinforcement are given in order to prevent a brittle failure, wide cracks and also to resist forces arising from restrained actions.

> **Note:** Additional rules concerning the minimum thickness of structural elements and the minimum reinforcement for all surfaces of members in bridges, with minimum bar diameter and maximum bar spacing for use in a Country may be found in its National Annex. No additional rules are recommended in this standard.

9.2 Beams

9.2.2 Shear reinforcement

(101) The shear reinforcement should form an angle α of between 45° and 90° to the longitudinal axis of the structural element.

> **Note:** Details of the form of shear reinforcement permitted for use in a Country may be found in its National Annex. The recommended forms are:
> - links enclosing the longitudinal tension reinforcement and the compression zone (see Figure 9.5 of EN 1992-1-1;
> - bent-up bars;
> - or a combination of the two.

(2) of EN 1992-1-1 does not apply.

9.5 Columns

9.5.3 Transverse reinforcement

(101) The diameter of the transverse reinforcement (links, loops or helical spiral reinforcement) should not be less than ϕ_{min} or one quarter of the maximum diameter of the longitudinal bars, whichever is the greater. The diameter of the wires of welded mesh fabric for transverse reinforcement should not be less than $\phi_{min,mesh}$.

> **Note:** The minimum diameter of transverse reinforcement for use in a Country may be found in its National Annex. The recommended values are ϕ_{min} = 6mm and $\phi_{min,mesh}$ = 5mm.

9.7 Deep beams

(102) The distance between two adjacent bars of the mesh should not exceed s_{mesh}.

> **Note:** The maximum spacing of adjacent bars for use in a Country may be found in its National Annex. The recommended value of s_{mesh} is the lesser of the web thickness or 300mm.

9.8 Foundations

9.8.1 Pile caps

(103) The main tensile reinforcement to resist the action effects should be concentrated in the stress zones between the tops of the piles. A minimum bar diameter d_{min} should be provided. If the area of this reinforcement is at least equal to the minimum reinforcement, evenly distributed bars along the bottom surface of the member may be omitted.

> **Note:** The value of d_{min} for use in a Country may be found in its National Annex. The recommended value is 12mm.

9.10 Tying systems

This clause does not apply.

SECTION 10 ADDITIONAL RULES FOR PRECAST CONCRETE ELEMENTS AND STRUCTURES

The following clauses of EN 1992-1-1 apply.

10.1.1	*10.5.1 (2)*	*10.5.4.1 (3)P*	*10.5.5.1 (2)P*
10.2 (1)P	*10.5.2 (1)*	*10.5.4.1 (4)P*	*10.5.5.1 (3)*
10.2 (2)	*10.5.2 (2)*	*10.5.4.2 (1)P*	*10.5.5.1 (4)P*
10.2 (3)	*10.5.3 (1)P*	*10.5.4.2 (2)P*	*10.5.5.1 (5)P*
10.3.1.1 (1)	*10.5.3 (2)P*	*10.5.4.2 (3)*	*10.5.5.2 (1)*
10.3.1.1 (2)	*10.5.3 (3)P*	*10.5.4.3 (1)*	*10.5.5.2 (2)*
10.3.1.1 (3)	*10.5.3 (4)*	*10.5.4.3 (2)*	*10.5.5.2 (3)*
10.3.1.2 (1)	*10.5.3 (5)*	*10.5.4.3 (3)*	*10.5.5.3 (1)P*
10.3.1.2 (2)	*10.5.3 (6)*	*10.5.4.3 (4)*	*10.5.5.3 (2)P*
10.3.1.2 (3)	*10.5.3 (7)*	*10.5.4.3 (5)*	*10.5.5.3 (3)P*
10.3.2.2 (1)P	*10.5.3 (8)*	*10.5.4.3 (6)*	*10.5.6.1 (1)P*
10.3.1.2 (2)	*10.5.3 (9)*	*10.5.4.4 (1)*	*10.5.6.2 (1)*
10.4.1 (1)P	*10.5.3 (10)*	*10.5.4.5 (1)P*	*10.5.6.2 (2)*
10.4.1 (2)	*10.5.3 (11)*	*10.5.4.5 (2)*	*10.5.6.2 (3)*
10.4.1 (3)	*10.5.3 (12)*	*10.5.4.6 (1)*	*10.5.6.3 (1)*
10.4.2 (1)	*10.5.4.1 (1)P*	*10.5.4.7 (1)*	*10.5.6.3 (2)*
10.5.1 (1)	*10.5.4.1 (2)P*	*10.5.5.1 (1)P*	*10.5.6.3 (3)*

10.1 General

(101)P The rules in this section apply to structures made partly or entirely of precast concrete elements, and are supplementary to the rules in other sections. Additional matters related to detailing, production and assembly are covered by specific product standards.

10.5.7 Tying systems

This clause does not apply.

SECTION 11 LIGHTWEIGHT AGGREGATE CONCRETE STRUCTURES

The following clauses of EN 1992-1-1 apply.

11.1 (1)P	*11.3.2 (1)*	*11.3.7 (1)*	*11.6.4.2 (1)*
11.1.1 (1)P	*11.3.2 (2)*	*11.4.1 (1)*	*11.6.4.2 (2)*
11.1.1 (2)P	*11.3.3 (1)*	*11.4.2 (1)P*	*11.6.5 (1)*
11.1.1 (3)	*11.3.3 (2)*	*11.5.1*	*11.6.6 (1)*
11.1.1 (4)P	*11.3.3 (3)*	*11.6.1 (1)*	*11.7 (1)P*
11.1.2 (1)P	*11.3.4 (1)*	*11.6.1 (2)*	*11.8.1 (1)*
11.2 (1)P	*11.3.5 (1)P*	*11.6.2 (1)*	*11.8.2 (1)*
11.3.1 (1)P	*11.3.5 (2)P*	*11.6.3.1 (1)*	*11.10 (1)P*
11.3.1 (2)	*11.3.6 (1)*	*11.6.4.1 (1)*	
11.3.1 (3)	*11.3.6 (2)*	*11.6.4.1 (2)*	

11.9 Detailing of members and particular rules

(101) The diameter of bars embedded in LWAC should not normally exceed 32 mm. For LWAC bundles of bars should not consist of more than two bars and the equivalent diameter should not exceed 45mm.

> **Note:** The use of bundled bars may be restricted by the National Annex.

SECTION 12 PLAIN AND LIGHTLY REINFORCED CONCRETE STRUCTURES

All the clauses of EN 1992-1-1 apply.

SECTION 113   DESIGN FOR THE EXECUTION STAGES

113.1 General

(101) For bridges built in stages, the design should take account of the construction procedure in the following circumstances:
   a. Where forces, other than those produced on the completed structure, occur in any structural section during the phases of construction (e.g. deck erection by incremental launching, piers of bridges built by balanced cantilever).
   b. Where redistribution of forces due to rheological effects is originated by changes to the structural arrangement during the construction process (e.g. continuous bridges built span by span on falsework or by cantilever).
   c. Where redistribution of stresses due to rheological effects is originated by changes to structural sections during the construction process (e.g. decks consisting of precast beams and an insitu slab).
   d. Where the erection or casting sequence may have an influence on: the stability of the structure during construction, the forces in the completed structure, or the geometry of the completed structure.

(102) For structures in which any of the circumstances described in paragraphs (101).a to d apply, the serviceability limit states and ultimate limit states should be verified at construction stages.

(103) For structures in which the circumstances described in paragraphs (101).b or c apply, long term values of forces or stresses should determined from an analysis of redistribution effects.   Step by step or approximate methods may be used in these calculations.

(104) For structures in which the circumstances described in paragraph (101).d apply, erection and casting sequences/procedures should be indicated on drawings or detailed in a construction procedure document.

113.2 Actions during execution

(101) The actions to be taken into account during execution are given in EN 1991-1-6 and annexes.

(102) For the ultimate limit state verification of structural equilibrium for segmental bridges built by balanced cantilever, unbalanced wind pressure should be considered. An uplift or horizontal pressure of at least x N/m^2 acting on one of the cantilevers should be considered.

   Note: The x value to be used in a Country may be found in its National Annex. The recommended characteristic value of x is 200 N/m².

(103) For verification of ultimate limit states in bridges built by in-situ balanced cantilever, an accidental action arising from a fall of formwork should be considered. The action should include for dynamic effects. The fall may occur in any construction stage. (traveller movement, casting, etc.)

(104) For balanced cantilever construction with precast segments, an accidental fall of one segment should be taken into account.

(105) For incrementally launched decks imposed deformations should be taken into account.

113.3 Verification criteria

113.3.1. Ultimate limit states

(101) See EN 1992-2 section 6.

113.3.2. Serviceability limit states

(101) The verifications for the execution stage should be the same as those for the completed structure, with the following exceptions.

(102) Serviceability criteria for the completed structure need not be applied to intermediate execution stages, provided that durability and final appearance of the completed structure are not affected (e.g. deformations).

(103) Even for bridges or elements of bridges in which the limit-state of decompression is checked under the quasi-permanent or frequent combination of actions on the completed structure, tensile stresses less than $k.f_{ctm}(t)$ under the quasi-permanent combination of actions during execution are permitted.

> **Note:** The value of k to be used in a Country may be found in its National Annex. The recommended value of k is 1,0.

(104) For bridges or elements of bridges in which the limit-state of cracking is checked under frequent combination on the completed structure, the limit state of cracking should be verified under the quasi-permanent combination of actions during execution.

ANNEX A (Informative)

Modification of partial factors for materials

All the clauses of EN 1992-1-1 apply.

ANNEX B (Informative)

Creep and shrinkage strain

The following clauses of EN 1992-1-1 apply.
B.1(1)   *B.1(2)*   *B.1(3)*   *B.2 (1)*

B.100 General

(101) This Annex may be used for calculating creep and shrinkage, including development with time. However, typical experimental values can exhibit a scatter of ± 30% around the values of creep and shrinkage amplitude given in this Annex. Where greater accuracy is required due to the structural sensitivity to creep and/or shrinkage, an experimental assessment of these effects and of the development of delayed strains with time should be undertaken. Section B.104 includes guidelines for the experimental determination of creep and shrinkage coefficients.

(102) For High Strength Concrete (f_{ck} > 50) an alternative approach to the evaluation of creep and shrinkage is given in Section B.103. The alternative approach takes account of the effect of adding silica fume and significantly improves the precision of the prediction.

(103) Furthermore, the expressions for creep in Sections B.1 and B.103 are valid when the the mean value of the concrete cylinder strength at the time of loading $f_{cm}(t_0)$ is greater that $0.6 f_{cm}$ ($f_{cm}(t_0)$ > 0,6 f_{cm}).
When concrete is to be loaded at earlier ages, with significant strength development at the beginning of the loading period, specific determination of the creep coefficient should be undertaken. This should be based on an experimental approach and the determination of a mathematical expression for creep should be based on the guidelines included in Section B.104.

(104) Creep and shrinkage formulae and experimental determinations are based on data collected over limited time periods. Extrapolating such results for very long-term evaluations (e.g. one hundred years) results in the introduction of additional errors associated with the mathematical expressions used for the extrapolation. When safety would be increased by overestimation of delayed strains, and when it is relevant in the project, the creep and shrinkage predicted on the basis of the formulae or experimental determinations should be multiplied by a safety factor, as indicated in Section B.105.

B.103 High Strength Concrete

(101) In the case of high strength concrete (HSC), namely for concrete strength classes greater than or equal to 55/67, the model described in this clause should be used to obtain better consistency with experimental data when the information required to utilise the model is available. For HSC without silica fume, creep is generally greater than predicted in the average expressions of Section B.1.

(102) The model makes a distinction between strains occurring in sealed concrete and additional deformation due to drying. Two expressions for shrinkage and two for creep, are given in this clause. The time-dependant strain components are :
- autogeneous shrinkage,
- drying shrinkage,

- basic creep,
- drying creep.
This distinguishes phenomena which are governed by different physical mechanisms. The autogeneous shrinkage is related to the hydration process whereas the drying shrinkage, due to humidity exchanges, is associated with the structure's environment.

(103) Specific formulae are given for silica-fume concrete (SFC). For the purpose of this clause, SFC is considered as concrete containing an amount of silica fume of at least 5% of the cementitious content by weight.

B.103.1   Autogeneous shrinkage

(101) The hydration rate governs the kinetics of autogeneous shrinkage. Therefore the hardening rate controls the progress of the phenomenon. The ratio $f_{cm}(t)/f_{ck}$, known as the maturity of young concrete, is taken as the main variable before 28 days. Shrinkage appears to be negligible for maturity less than 0.1. For ages beyond 28 days, the variable governing the evolution of autogeneous shrinkage is time.
The model for evaluation of autogeneous shrinkage is as follows:

- for t < 28 days,

  - if $\dfrac{f_{cm}(t)}{f_{ck}} < 0.1$ $\varepsilon_{ca}(t, f_{ck}) = 0$ (B.101)

  - if $\dfrac{f_{cm}(t)}{f_{ck}} \geq 0.1$ $\varepsilon_{ca}(t, f_{ck}) = (f_{ck} - 20)\left(2,2\dfrac{f_{cm}(t)}{f_{ck}} - 0.2\right)10^{-6}$ (B.102)

where ε_{ca} is the autogeneous shrinkage occurring between setting and time t. In cases where this strength $f_{cm}(t)$ is not known, it can be evaluated in accordance with 3.1.2(6) of EN 1992-1-1.

- for t ≥ 28 days,

$$\varepsilon_{ca}(t, f_{ck}) = (f_{ck} - 20)[2.8 - 1.1\exp(-t/96)]10^{-6} \tag{B.103}$$

Therefore, according to this model, 97% of total autogeneous shrinkage has occurred after 3 months.

B.103.2 Drying shrinkage

(101) Due to self-desiccation, internal humidity decreases with time in sealed HSC and it tends to a final value which is inversely related to the compressive strength at 28 days.
The expression for desiccation shrinkage is as follows :

$$\varepsilon_{cd}(t, t_s, f_{ck}, h_0, \rho_h) = \frac{K(f_{ck})[72\exp(-0.046f_{ck}) + 75 - RH](t - t_s)}{(t - t_s) + \beta_{cd}h_0^2} \tag{B.104}$$

with : $K(f_{ck}) = 18$ if $f_{ck} \leq 57$ MPa
            $K(f_{ck}) = 30 - 0.21f_{ck}$ if $f_{ck} \geq 57$ MPa.

$$\beta_{cd} = \begin{pmatrix} 0.007 & for\ silica - fume\ concrete \\ 0.021 & for\ non\ silica - fume\ concrete \end{pmatrix}$$

B.103.3 Creep

(101) The delayed stress dependent strain, $\varepsilon_{cc}(t,t_0)$, i.e. the sum of basic and drying creep, can be calculated by the following expression :

$$\varepsilon_{cc}(t,t_0) = \frac{\sigma(t_0)}{E_{c28}}[\Phi_b(t,t_0) + \Phi_d(t,t_0)] \tag{B.105}$$

B.103.4 Basic creep

(101) The final basic creep coefficient of silica fume concrete has been found to depend on the strength at loading $f_{cm}(t_0)$. Furthermore, the younger the concrete at loading, the faster the deformation. However this tendency has not been observed for non silica-fume concrete. For this material, the creep coefficient is assumed to remain constant at a mean value of 1.4. The kinetics term is therefore a function of the maturity, expressed by the quantity $f_{cm}(t)/f_{ck}$. The equation is :

$$\Phi_b(t,t_0,f_{ck},f_{cm}(t_0)) = \phi_{b0}\frac{\sqrt{t-t_0}}{[\sqrt{t-t_0} + \beta_{bc}]} \tag{B.106}$$

with :

$$\phi_{b0} = \begin{pmatrix} \dfrac{3.6}{f_{cm}(t_0)^{0,37}} & for\ silica - fume\ concrete \\ \\ 1.4 & for\ non\ silica - fume\ concrete \end{pmatrix} \tag{B.107}$$

and

$$\beta_{bc} = \begin{pmatrix} 0.37\exp\left(2.8\dfrac{f_{cm}(t_0)}{f_{ck}}\right) & for\ silica - fume\ concrete \\ \\ 0.4\exp\left(3.1\dfrac{f_{cm}(t_0)}{f_{ck}}\right) & for\ non\ silica - fume\ concrete \end{pmatrix} \tag{B.108}$$

For loadings applied after 28 days, the actual compressive strength should be evaluated. If measurements of concrete strength are not available, a value of $1.2f_{ck}$ may be taken for old concrete.

B.103.5 Drying creep

(101)The drying creep, which is very low for silica fume concrete, is evaluated with reference to the drying shrinkage occurring during the same period. The drying creep coefficient may be expressed by the following simplified equation:

$$\Phi_d(t,t_s,t_0,f_{ck},RH,h_0) = \phi_{d0}[\varepsilon_{cd}(t,t_s) - \varepsilon_{cd}(t_0,t_s)] \tag{B.109}$$

With :

$$\phi_{d0} = \begin{cases} 1000 & \text{for silica - fume concrete} \\ \\ 3200 & \text{for non silica - fume concrete} \end{cases}$$

B.104 Experimental identification procedure

(101) In order to evaluate delayed strains with greater precision, it may be necessary to identify the parameters included in the models describing creep and shrinkage from experimental measurements. The following procedure, based on the experimental determination of coefficients altering the formulae of Section B.103, may be used.

(102) Experimental data may be obtained from appropriate shrinkage and creep tests both in autogeneous and drying conditions. The measurements should be obtained under controlled conditions and recorded for at least 6 months.

B.104.1 Autogeneous shrinkage

(101) The autogeneous shrinkage model has to be separated in to two parts.

- for t < 28 days,

- if $\dfrac{f_{cm}(t)}{f_{ck}} \geq 0.1$
$$\varepsilon_{ca}(t,f_{ck}) = \beta_{ca1}(f_{ck} - 20)\left(2.2\dfrac{f_{cm}(t)}{f_{ck}} - 0.2\right)10^{-6} \qquad \text{(B.110)}$$

The parameter β_{ca1} has to be chosen in order to minimise the sum of the squares of the differences between the model estimation and the experimental results from the beginning of the measurement to 28 days.

- for t ≥ 28 days,
$$\varepsilon_{ca}(t,f_{ck}) = \beta_{ca1}(f_{ck} - 20)[\beta_{ca2} - \beta_{ca3}\exp(-t/\beta_{ca4})]10^{-6} \qquad \text{(B.111)}$$

The other parameters β_{ca2}, β_{ca3}, β_{ca4} are then chosen using the same method.

B.104.2 Drying shrinkage

(101) Due to self-desiccation, internal humidity decreases with time in sealed HS/HPC,

$$\varepsilon_{cd}(t,t_s,f_{ck},h_0,\rho_h) = \beta_{cd1}\dfrac{K(f_{ck})[72\exp(-0.046f_{ck}) + 75 - RH](t - t_s)}{(t - t_s) + \beta_{cd2}h_0^2} \qquad \text{(B.112)}$$

The parameters β_{cd1}, β_{cd2} have to be chosen in order to minimise the sum of the squares of the differences between the model estimation and the experimental results.

B.104.3 Basic creep

(101) Two parameters have to be identified, a global one β_{cd1} which is applied to the entire expression for basic creep,

$$\Phi_b(t,t_0,f_{ck},f_{cm}(t_0)) = \beta_{cd1}\phi_{b0}\frac{\sqrt{t-t_0}}{\left[\sqrt{t-t_0} + \beta_{bc}\right]}$$ (B.113)

and β_{bc2} which is included in β_{bc} :

$$\beta_{bc} = \begin{cases} \beta_{bc2}\exp\left(2.8\dfrac{f_{cm}(t_0)}{f_{ck}}\right) & \text{for silica} - \text{fume concrete} \\[4mm] \beta_{bc2}\exp\left(3.1\dfrac{f_{cm}(t_0)}{f_{ck}}\right) & \text{for non silica} - \text{fume concrete} \end{cases}$$ (B.114)

These two parameters have to be determined by minimising the sum of the square of the difference between experimental results and model estimation.

B.104.4 Drying creep

(101) Only the global parameter ϕ_{d0} has to be identified.

$$\Phi_d(t,t_s,t_0,f_{ck},RH,h_0) = \phi_{d0}\left[\varepsilon_{cd}(t,t_s) - \varepsilon_{cd}(t_0,t_s)\right]$$ (B.115)

B.105 Long term delayed strain estimation

(101) Creep and shrinkage formulae and experimental determinations are based on data collected over limited periods of time. Extrapolating such results for very long-term evaluations (e.g. one hundred years) results in the introduction of additional errors associated with the mathematical expressions used for the extrapolation.

(102) The formulae given in Sections B.1, B.2 and B.103 of this Annex provide a satisfactory average estimation of delayed strains extrapolated to the long-term. However, when safety would be increased by overestimation of delayed strains, and when it is relevant in the project, the creep and shrinkage predicted on the basis of the formulae or experimental determinations should be multiplied by a safety factor.

(103) In order to take into account uncertainty regarding the real long term delayed strains in concrete (ie. uncertainty related to the validity of extrapolating mathematical formulae fitting creep and shrinkage measurements on a relatively short period), the following safety factor γ_{lt} can be included. Values for γ_{lt} are given in Table B.101

Table B.101: Safety factor for long-term extrapolation of delayed strains, when relevant.

t (age of concrete for estimating the delayed strains)	γ_{lt}
t < 1 year	1
t = 5 years	1.07

t = 10 years	1.1
t = 50 years	1.17
t = 100 years	1.20
t = 300 years	1.25

which corresponds to the following mathematical expression :

$$
\begin{cases}
t \leq 1\,year & \gamma_{lt} = 1 \\
t \geq 1\,year & \gamma_{lt} = 1 + 0{,}1\log\left(\dfrac{t}{t_{ref}}\right) \quad with \quad t_{ref} = 1\,year
\end{cases}
\tag{B.116}
$$

For concrete aged less than one year the B1, B2 and B103 expressions can be used directly, since they correspond to the duration of the experiments used for formulae calibration.

For concrete aged 1 year or more, and thus especially for long-term evaluations of deformations, the expressions given in parts B1, B2 or B103 (amplitude of delayed strains at time t) have to be multiplied by γ_{lt}.

ANNEX C (Normative)

Properties of reinforcement suitable for use with this Eurocode

All the clauses of EN 1992-1-1 apply.

ANNEX D (Informative)

Detailed calculation method for prestressing steel relaxation losses

All the clauses of EN 1992-1-1 apply.

Annex E (Informative)

Indicative strength classes for durability

All the clauses of EN 1992-1-1 apply.

Annex F (Informative)

> **Note:** The sign convention used in this Annex follows that in EN 1992-1-1 and is different to that used in Section 6.9, Annex LL and Annex MM of this standard.

Tension reinforcement expressions for in-plane stress conditions

The following clauses of EN 1992-1-1 apply.
F.1 (1)   *F.1 (2)*   *F.1 (3)*   *F.1 (5)*

F.1 General

(104) In locations where σ_{Edy} is tensile or $\sigma_{Edx} \cdot \sigma_{Edy} \leq \tau^2_{Edxy}$, reinforcement is required.

The optimum reinforcement, corresponding to $\theta = 45°$, is indicated by superscript ', and related concrete stress are determined by:

For $\sigma_{Edx} \leq |\tau_{Edxy}|$

$$f'_{tdx} = |\tau_{Edxy}| - \sigma_{Edx} \tag{F.2}$$

$$f'_{tdy} = |\tau_{Edxy}| - \sigma_{Edy} \tag{F.3}$$

$$\sigma_{cd} = 2|\tau_{Edxy}| \tag{F.4}$$

For $\sigma_{Edx} > |\tau_{Edxy}|$

$$f'_{tdx} = 0 \tag{F.5}$$

$$f'_{tdy} = \frac{\tau^2_{Edxy}}{\sigma_{Edx}} - \sigma_{Edy} \tag{F.6}$$

$$\sigma_{cd} = \sigma_{Edx}\left(1 + \left(\frac{\tau_{Edxy}}{\sigma_{Edx}}\right)^2\right) \tag{F.7}$$

The concrete stress, σ_{cd}, should be checked with a realistic model of cracked sections (see Section 6.109 'Membrane elements' in EN 1992-2).

> **Note:** The minimum reinforcement is obtained if the directions of reinforcement are identical to the directions of the principal stresses.

Alternatively, for the general case the necessary reinforcement and the concrete stress may be determined by:

$$f_{tdx} = |\tau_{Edxy}|\cot\theta - \sigma_{Edx} \tag{F.8}$$

$$f_{tdy} = |\tau_{Edxy}|/\cot\theta - \sigma_{Edy} \tag{F.9}$$

$$\sigma_{cd} = |\tau_{Edxy}|\left(\cot\theta + \frac{1}{\cot\theta}\right) \tag{F.10}$$

where θ is the angle of the principal concrete compressive stress to the *x*-axis.

Note: The value of $\cot\theta$ should be chosen to avoid compression values of f_{td}.

In order to avoid unacceptable cracks for the serviceability limit state, and to ensure the required deformation capacity for the ultimate limit state, the reinforcement derived from Expressions (F.8) and (F.9) for each direction should not be more than twice and not less than half the reinforcement determined by expressions (F2) and (F3) or (F5) and (F6). These limitations are expressed by $\frac{1}{2}f'_{tdx} \leq f_{tdx} \leq 2f'_{tdx}$ and $\frac{1}{2}f'_{tdy} \leq f_{tdy} \leq 2f'_{tdy}$.

Annex G (Informative)

Soil structure interaction

All the clauses of EN 1992-1-1 apply.

Annex H (Informative)

Global second order effects in structures

This Annex does not apply

Annex I (Informative)

Analysis of flat slabs and shear walls

The following clauses of EN 1992-1-1 apply.
I.1.1 (1)	*I.1.2 (1)*	*I.1.2 (3)*
I.1.1 (2)	*I.1.2 (2)*	

I.1.2 Equivalent frame analysis

(4) and (5) of EN 1992-1-1 do not apply

I.1.3   Irregular column layout

This clause does not apply

I.2 Shear walls

This clause does not apply

Annex J (Informative)

Detailing rules for particular situations

The following clauses of EN 1992-1-1 apply.

J.1 (4)	*J.2.2 (2)*	*J.3 (1)*	
J.1 (5)	*J.2.2 (3)*	*J.3 (2)*	

J.104 Partially loaded areas

J.104.1 Bearing zones of bridges

(101) The design of bearing zones of bridges should be in accordance with the rules given in this clause in addition to those in 6.5 and 6.7 of EN 1992-1-1.

(102) The distance from the edge of the loaded area to the free edge of the concrete section should not be less than 1/6 of the corresponding dimension of the loaded area measured in the same direction. In no case should the distance to the free edge be taken as less than 50 mm.

(103) For concrete classes equal to or higher than C55/67, f_{cd} in formula (6.63) of EN 1992-1-1 should be substituted by $\dfrac{0,46.f_{ck}^{2/3}}{1+0,1.f_{ck}}.f_{cd}$.

(104) In order to avoid edge sliding, uniformly distributed reinforcement parallel to the loaded face should be provided to the point at which local compressive stresses are dispersed. This point is determined as follows: A line inclined at an angle θ (30°) to the direction of load application is drawn from the edge of the section to intersect with the opposite edge of the loaded surface, as shown in Figure J.107. The reinforcement provided to avoid edge sliding shall be adequately anchored.

Figure J.107 : Edge sliding mechanism

(105) The reinforcement provided in order to avoid edge sliding (A_r) should be calculated in accordance with the expression $A_r . f_{yd} \geq F_{Rdu} / 2$

J.104.2. Anchorage zones of post-tensioned members

(101) The following rules apply in addition to those in 8.10.3 of EN 1992-1-1 for the design of anchorage zones where two or more tendons are anchored.

(102) The bearing stress behind anchorage plates should be checked as follows :

- The minimum distance between the centreline of the anchorage and the edge of the concrete should not be less than that specified in the appropriate European Technical Approval. This minimum value depends on the strength of the concrete at the time of tensioning.

- The reinforcement required to prevent bursting and spalling in anchorage zones is determined in relation to a rectangular prism of concrete, known as the primary regularisation prism, located behind each anchorage. The cross section of the prism associated with each anchorage is known as the associate rectangle. The associate rectangle has the same centre and the same axes of symmetry as the anchorage plate (which should have two axes of symmetry) and should satisfy :

$$\frac{P_{max}}{c \cdot c'} \le 0,6 \cdot f_{ck}(t) \qquad (J.101)$$

where
   P_{max} is the maximum force applied to the tendon according to 5.10.2.1 of EN 1992-1-1
   c, c' are the dimensions of the associate rectangle
   $f_{ck}(t)$ is the concrete strength at the time of tensioning

The associate rectangle should have approximately the same aspect ratio as the anchorage plate. This requirement is satisfied if c/a and c'/a' are not greater than $1,25\sqrt{\dfrac{c \cdot c'}{a \cdot a'}}$ where a and a' are the dimensions of the smallest rectangle including the anchorage plate.

- Rectangles associated with anchorages located in the same cross section should remain inside the concrete and should not overlap
- The "primary regularisation prism" represents very approximately the volume of concrete in which the stresses change from very high values just behind the anchorage plate to a reasonable value for concrete under uniaxial compression. The axis of the prism is taken as the axis of the tendon, its base is the associate rectangle and its depth behind the anchorage is taken as $1,2.Max(c, c')$. The prisms associated with different anchorages may overlap (this can occur when the tendons are not parallel) but should remain inside the concrete.

(103) Reinforcement to prevent bursting and spalling of the concrete, in each regularisation prism (as defined in rule (102) above) should not be less than:

$$A_s = 0,15 \frac{P_{max}}{f_{yd}} \gamma_{p,\,unfav} \qquad \text{with} \quad \gamma_{p,unfav} \geq 1,20$$

(J.102)

where P_{max} is the maximum force applied to the tendon according to 5.10.2.1 expression (5.41) of EN 1992-1-1 and f_{yd} is the design strength of the reinforcing steel.

This reinforcement should be distributed in each direction over the length of the prism. The area of the surface reinforcement at the loaded face should not be less than $0,03 \frac{P_{max}}{f_{yd}} \gamma_{p,\,unfav}$ in each direction.

(104) The minimum reinforcement derived from the appropriate European Technical Approval for the prestressing system should be provided. The arrangement of the reinforcement should be modified if it is utilised to withstand the tensile forces calculated according to 8.10.3 (4) of EN 1992-1-1.

Annex KK (Informative)

Structural effects of time dependent behaviour of concrete

KK.1 Introduction

This Annex describes different methods of evaluating the time dependent effects of concrete behaviour.

KK.2 General considerations

(101) Structural effects of time dependent behaviour of concrete, such as variation of deformation and/or of internal actions, shall be considered, in general, in serviceability conditions.

> **Note:** In particular cases (e.g. structures or structural elements sensitive to second order effects or structures, in which action effects cannot be redistributed) time dependent effects may also have an influence at ULS.

(102) When the compressive stresses in concrete are less than $0,45 \ f_{ck}(t)$ under the quasi permanent combination, a linear structural analysis and a linear ageing viscoelastic model is appropriate. The time dependent behaviour of concrete should be described by the creep coefficient $\varphi(t,t_0)$ or the creep function $J(t,t_0)$ or, alternatively, by the relaxation function $R(t,t_0)$
For higher compressive stresses, non-linear creep effects should be considered.

(103) Time dependent analysis for the evaluation of deformation and internal actions of rigid restrained reinforced and prestressed concrete structures may be carried out assuming them to be homogeneous and the limited variability of concrete properties in different regions of the structure may be ignored. Any variation in restraint conditions during the construction stages or the lifetime of the structure should be taken into account in the evaluation.

(104) Different types of analysis and their typical applications are shown in Table KK 101.

Table KK.101 : Type of analysis

Type of analysis	Comment and typical application
General and incremental step-by-step method	These are general methods and are applicable to all structures. Particularly useful for verification at intermediate stages of construction in structures where properties vary along the length (e.g. cantilever construction).
Methods based on the theorems of linear viscoelasticity	Applicable to homogeneous structures with rigid restraints.
The ageing coefficient method	This method will be useful when only the long - term distribution of forces and stresses are required. Applicable to bridges with composite sections (precast beams and in-situ concrete slabs).
Simplified ageing coefficient method	Applicable to structures that undergo changes in support conditions (e.g. span-to- span or

| | free cantilever construction). |

The following assumptions are made in all the methods noted above:

- Creep and shrinkage are considered independent of each other.
- For each type of concrete in a section, average creep and shrinkage properties are adopted ignoring any minor differences at different locations.
- The principle of superposition is valid for the assessment of total deformation due to actions applied at various ages.

Brief outline details of some of the methods are given in the following sections.

KK.3 General Method

(101) The following assumptions are made:

a) The fundamental equation for time dependent concrete strain is:

$$\varepsilon_c(t) = \frac{\sigma_0}{E_c(t_0)} + \varphi(t,t_0)\frac{\sigma_0}{E_c(28)} + \sum_{i=1}^{n}\left(\frac{1}{E_c(t_i)} + \frac{\varphi(t,t_i)}{E_c(28)}\right)\Delta\sigma(t_i) + \varepsilon_{cs}(t,t_s) \qquad (KK.101)$$

In this equation, the first term represents the instantaneous deformations due to a stress applied at t_0. The second term represents the creep due to this stress. The third term represents the sum of the instantaneous and creep deformations due to the variation in stresses occurring at instant t_i. The fourth term represents the shrinkage deformation.

b) Reinforcing steel is assumed to behave linearly under instantaneous loads. When the stress in pre-stressing steel is greater than $0.5f_{pmax}$ relaxation and a variable state of deformation should be taken into account.

c) Perfect bond exists between concrete and the bonded steel.

d) In the case of linear elements, sections are assumed to be plane before and after deformation.

e) Equilibrium and compatibility are maintained.

(102) Concrete creep at each section depends on its stress history. This is accounted for by a step-by-step process. Structural analysis is carried out at successive time intervals maintaining conditions of equilibrium and compatibility and using the basic properties of materials relevant at the time under consideration. The deformation is computed at successive time intervals using the variation of concrete stress in the previous time interval.

KK.4 Incremental method

(101) At time t where the applied stress is σ, the creep strain $\varepsilon_{cc}(t)$, the potential creep strain $\varepsilon_{\infty cc}(t)$ (ie. the creep strain that would be reached at time t = ∞, if the stress applied at time t were kept constant) and the creep rate are theoretically derived from the whole loading history.

(102) The potential creep strain at time t may be evaluated using the principle of superposition (for notations, see formula (KK.101) and EN 1992-1-1 Annex B) :

$$\frac{d\varepsilon_{\infty cc}(t)}{dt} = \frac{d\sigma}{dt}\frac{\varphi(\infty,t)}{E_{c28}}$$

(KK.102)

(103) At time t, it is possible to define an equivalent time t_e such that, under a constant stress applied from time t_e, the same creep strain and the same potential creep strain are obtained ; t_e fulfils the equation :

$$\varepsilon_{\infty cc}(t)\cdot \beta_c(t,t_e) = \varepsilon_{cc}(t)$$

(KK.103)

The creep rate at time t can thus be calculated using the creep curve corresponding to the equivalent loading time :

$$\frac{d\varepsilon_{cc}(t)}{dt} = \varepsilon_{\infty cc}(t)\frac{\partial \beta_c(t,t_e)}{\partial t}$$

(KK.104)

(104) When $|\varepsilon_{cc}(t)|>|\varepsilon_{\infty cc}(t)|$, which particularly applies to the case of creep unloading, t_e is defined relative to the current phase and accounts for the sign change of the applied stress. It reads :

$$\varepsilon_{ccMax}(t) - \varepsilon_{cc}(t) = \left(\varepsilon_{ccMax}(t) - \varepsilon_{\infty cc}(t)\right)\cdot \beta_c(t,t_e)$$

(KK.105)

$$\frac{d\left(\varepsilon_{ccMax}(t) - \varepsilon_{cc}(t)\right)}{dt} = \left(\varepsilon_{ccMax}(t) - \varepsilon_{\infty cc}(t)\right)\cdot \frac{\partial \beta_c(t,t_e)}{\partial t}$$

(KK.106)

where $\varepsilon_{ccMax}(t)$ is the last extreme creep strain reached before time t.

KK.5 Application of theorems of linear viscoelasticity

(101) In structures with rigid restraints, stresses and deformations may initially evaluated by means of an elastic analysis of the structure in which the elastic modulus is assumed to be constant.

(102) Time dependant properties of concrete are fully characterised by the creep function J (t,t_0) and the relaxation function $R(t,t_0)$, where:

J (t,t_0) represents the total stress dependant strain per unit stress, i.e. the strain response at time "t" resulting from a sustained and constant imposed unit stress applied at time "t_0"

R (t,t_0) represents the stress response at time "t" resulting from a sustained and constant imposed unit stress-dependant strain applied at time " t_0"

(103) Under direct actions (imposed loads) the elastic stresses are not modified by creep. The deformations may be evaluated at time "t" by integration of elastic strain increments factored by the creep factor J $(t,\tau)\cdot E_C$

$$S(t) = S_{el}(t_0)$$

(KK.107)

$$D(t) = E_C\int_0^t J(t,\tau)dD_{el}(\tau)$$

(KK.108)

(104) Under indirect actions (imposed deformations) the elastic deformations are not modified by creep. The stresses may be evaluated at time "t" by integration of the elastic stress increments factored by the relaxation factor R $(t,\tau)/E_C$

$$D(t) = D_{el}(t_0) \tag{KK.109}$$

$$S(t) = \frac{1}{E_C} \int_0^t R(t,\tau) dS_{el}(\tau) \tag{KK.110}$$

(105) In a structure subjected to imposed constant loads, whose initial static scheme (101) is modified into a final scheme (102) by the introduction of additional restraint at time $t_1 \geq t_0$ (t_0 being the structure age at loading), the stress distribution evolves for $t>t_1$ and approaches that corresponding to the load application in the final static scheme

$$S_2(t) = S_{el,1} + \xi(t,t_0,t_1) \Delta S_{el,1} \tag{KK.111}$$

where:

$S_2(t)$ is the stress distribution for $t>t_1$ in the structure with modified restraints;

$S_{el,1}$ is the elastic stress distribution in the initial static scheme;

$\Delta S_{el,1}$ is the correction to be applied to the elastic solution $S_{el,1}$ to comply with the elastic solution related to the load application in the final static scheme.

$\xi(t,t_0,t_1)$ is the redistribution function

$$\xi(t,t_0,t_1) = \int_{t_1}^t R(t,\tau) dJ(\tau,t_0) \tag{KK.112}$$

with $0 \leq \xi(t,t_0,t_1) \leq 1$

and $\xi(t,t_0,t_0^+) = 1 - \dfrac{R(t,t_0)}{E_C(t_0)}$ \hfill (KK.113)

(106) In cases in which the transition from the initial static scheme to the final scheme is reached by means of several different restraint modifications applied at different times $t_i \geq t_0$, the stress variation induced by creep, by the effect of applying a group Δn_j of additional restraints at time t_j, is independent of the history of previous additional restraints introduced at times $t_i < t_j$ and depends only on the time t_j of application of Δn_j restraints

$$S_{j+1} = S_{el,1} + \sum_{i=1}^{j} \xi(t,t_0,t_i) \Delta S_{el,i} \tag{KK.114}$$

KK.6 Ageing coefficient method

(101) The ageing coefficient method enables variations in stress, deformation, forces and movements due to the time-dependant behaviour of the concrete and the prestressing steel at infinite time to be calculated without discrete time related analysis. In particular, on a section level, the changes in axial deformation and curvature due to creep, shrinkage and relaxation may be determined using a relatively simple procedure.

(102) The deformation produced by stress variations with time in the concrete may be taken as that which would result from an increase in stress applied and maintained from an intermediate .

$$\int_{\tau=t_0}^{t}(1+\varphi(t,\tau))d\sigma(\tau)=(1+\chi(t,t_0)\varphi(t,t_0))\Delta\sigma_{t_0\to t}$$ (KK.118)

where χ is the ageing coefficient. The value of χ may be determined at any given moment, by means of a step-by-step calculation or may be taken as being equal to 0.80 for t = ∞.

Relaxation at variable deformation may be evaluated in a simplified manner at infinite time as being the relaxation at constant length, multiplied by a reduction factor of 0.80.

KK.7 Simplified formulae

(101) Forces at time t_∞ may be calculated for those structures that undergo changes in support conditions (span-to-span construction, free cantilever construction, movements at supports, etc.) using a simplified approach. In these cases, as a first approximation, the internal force distribution at t $_\infty$ may be taken as

$$S_\infty = S_0 + (S_c - S_0)\frac{\varphi(\infty,t_0)-\varphi(t_c,t_0)}{1+\chi\varphi(\infty,t_c)}$$ (KK.119)

where:
    S_0 represents the internal forces at the end of the construction process.
    S_c represents the internal forces that are obtained if the structure is constructed on centering.
    t_0 is the concrete age on application of the load.
    t_c is the age of the concrete when the support conditions are changed.

Annex LL (Informative)

Concrete shell elements

(101) This section applies to shell elements, in which there are generally eight components of internal forces. The eight components of internal forces are listed below and shown in Figure LL.1:
- 3 plate components n_{Edx} , n_{Edy} , $n_{Edxy} = n_{Edyx}$
- 3 slab components m_{Edx} , m_{Edy} , $m_{Edxy} = m_{Edyx}$
- 2 transverse shear forces v_{Edx} , v_{Edy}

Figure LL.1: Shell element

(102) The first stage in the verification procedure is to establish if the shell element is uncracked or cracked.
Figure LL.2: The sandwich model

(103) In uncracked elements the only verification required is to check that the minimum principal stress is smaller than the design compressive strength f_{cd}. It may be appropriate to take into account the multiaxial compression state in the definition of f_{cd}.

(104) In cracked elements a sandwich model should be used for design or verification of the shell element.

(105) In the sandwich model three layers are identified (Figure LL.2): the two outer layers resist the membrane actions arising from n_{Edx}, n_{Edy}, n_{Edxy}, m_{Edx}, m_{Edy}, m_{Edxy}; and the inner layer carries the shear forces v_{Edx}, v_{Edy}. The thickness of the different layers should be established by means of an iterative procedure (see rules (113) to (115)).

(106) The inner layer should be designed according to 6.2, taking into account the principal shear, its principal direction and the longitudinal reinforcement components in that direction (see rules (113) to (115))

(107) In order to establish whether shell elements are cracked, the principal stresses at different levels within the thickness of the element should be checked. In practice the following inequality should be verified:

$$\Phi = \alpha \frac{J_2}{f_{cm}^2} + \lambda \frac{\sqrt{J_2}}{f_{cm}} + \beta \frac{I_1}{f_{cm}} - 1 \le 0 \tag{LL.101}$$

where:

$$J_2 = \frac{1}{6}\left[(\sigma_1 - \sigma_2)^2 + (\sigma_2 - \sigma_3)^2 + (\sigma_3 - \sigma_1)^2\right] \tag{LL.102}$$

$$J_3 = (\sigma_1 - \sigma_m)(\sigma_2 - \sigma_m)(\sigma_3 - \sigma_m) \tag{LL.103}$$

$$I_1 = \sigma_1 + \sigma_2 + \sigma_3 \tag{LL.104}$$

$$\sigma_m = (\sigma_1 + \sigma_2 + \sigma_3)/3 \tag{LL.105}$$

$$\alpha = \frac{1}{9k^{1.4}} \tag{LL.106}$$

$$\lambda = c_1 \cos\left[\frac{1}{3}\operatorname{ar\,cos}(C_2 \cos 3\theta)\right] \qquad \text{for} \quad \cos 3\theta \ge 0$$

$$\lambda = c_1 \cos\left[\frac{\pi}{3} - \frac{1}{3}\operatorname{ar\,cos}(-C_2 \cos 3\theta)\right] \quad \text{for} \quad \cos 3\theta < 0 \tag{LL.107}$$

$$\beta = \frac{1}{3,7k^{1.1}} \tag{LL.108}$$

$$\cos 3\theta = \frac{3\sqrt{3}}{2} \frac{J_3}{J_2^{3/2}} \tag{LL.109}$$

$$c_1 = \frac{1}{0,7k^{0,9}} \tag{LL.110}$$

$$c_2 = 1 - 6,8(k - 0,07)^2 \tag{LL.111}$$

$$k = \frac{f_{cm}}{f_{ctm}} \tag{LL.112}$$

If inequality (LL.101) is satisfied, then the element is considered to be uncracked; otherwise it should be considered as cracked.

(108) If the shell element is considered to be cracked, the forces within the outer layers of the sandwich model should be determined according to the following equations (figures LL.3a and LL.3b)

$$n_{Edxs} = n_{Edx} \frac{z_x - y_{xs}}{z_x} + \frac{m_{Edx}}{z_x} \tag{LL.113}$$

$$n_{Edxi} = n_{Edx} \frac{z_x - y_{xi}}{z_x} - \frac{m_{Edx}}{z_x} \tag{LL.114}$$

$$n_{Edys} = n_{Edy} \frac{z_y - y_{ys}}{z_y} + \frac{m_{Edy}}{z_y} \tag{LL.115}$$

$$n_{Edyi} = n_{Edy} \frac{z_y - y_{yi}}{z_y} - \frac{m_{Edy}}{z_y} \tag{LL.116}$$

$$n_{Edyxs} = n_{Edyx} \frac{z_{yx} - y_{yxs}}{z_{yx}} - \frac{m_{Edyx}}{z_{yx}} \tag{LL.117}$$

$$n_{Edyxi} = n_{Edyx} \frac{z_{yx} - y_{yxi}}{z_{yx}} + \frac{m_{Edyx}}{z_{yx}} \tag{LL.118}$$

$$n_{Edxys} = n_{Edxy} \frac{z_{xy} - y_{xys}}{z_{xy}} - \frac{m_{Edxy}}{z_{xy}} \tag{LL.119}$$

$$n_{Edxyi} = n_{Edxy} \frac{z_{xy} - y_{xyi}}{z_{xy}} + \frac{m_{Edxy}}{z_{xy}} \tag{LL.120}$$

where:
- z_x and z_y are the lever arms for bending moments and membrane axial forces;
- y_{xs}, y_{xi}, y_{ys}, y_{yi}, are the distances from the centre of gravity of the reinforcement to mid-plane of the element in the x and y directions, in relation to bending and axial membrane forces; therefore $z_x = y_{xs} + y_{xi}$ and $z_y = y_{ys} + y_{yi}$;
- y_{yxs}, y_{yxi}, y_{xys}, y_{xyi}, are the distances from the centre of gravity of the reinforcement to mid-plane of the element, in relation to torque moment and shear membrane forces; therefore $z_{yx} = y_{yxs} + y_{yxi}$ and $z_{xy} = y_{xys} + y_{xyi}$;
**Figure LL.3a: Axial actions and bending moments in the outer layer**

Figure LL.3b: Membrane shear actions and twisting moments in the outer layer

Out of plane shear forces v_{Edx} and v_{Edy} are applied to the inner layer with the lever arm, z_c, determined with reference to the centroid of the appropriate layers of reinforcement.

(109) For the design of the inner layer the principal shear v_{Edo} and its direction φ_o should be evaluated as follows:

$$v_{Edo} = \sqrt{{v_{Edx}}^2 + {v_{Edy}}^2}$$ (LL.121)

$$\tan \varphi_o = \frac{v_{Edy}}{v_{Edx}}$$ (LL.122)

(110) In the direction of principal shear the shell element behaves like a beam and the appropriate design rules should therefore be applied. In particular clause 6.2.2 should be

applied for members not requiring shear reinforcement and clause 6.2.3 should be applied for members requiring shear reinforcement. In expression (6.2.a) ρ_l should be taken as:

$$\rho_l = \rho_x \cos^2 \varphi_o + \rho_y \, sen^2 \varphi_o \qquad \text{(LL.123)}$$

(111) When shear reinforcement is necessary, the longitudinal force resulting from the truss model $V_{Edo}\cot\theta$ gives rise to the following membrane forces in x and y directions:

$$n_{Edyc} = \frac{v_{Edy}^2}{v_{Edo}} \cot \theta \qquad \text{(LL.124)}$$

$$n_{Edxyc} = \frac{v_{Edx} v_{Edy}}{v_{Edo}} \cot \theta \qquad \text{(LL.125)}$$

$$n_{Edxc} = \frac{v_{Edx}^2}{v_{Edo}} \cot \theta \qquad \text{(LL.126)}$$

$$n_{Edyxc} = n_{Edxyc} = \frac{v_{Edx} v_{Edy}}{v_{Edo}} \cot \theta \qquad \text{(LL.127)}$$

(112) The outer layers should be designed as membrane elements, using the design rules of clause 6 (109) and Annex F.

(113) The following simplified approach may generally be adopted with respect to figures LL.3a and LL.3b:

$$y_{ns} = y_{xs} = y_{ys} \qquad \text{(LL.128)}$$

$$y_{ni} = y_{xi} = y_{yi} \qquad \text{(LL.129)}$$

$$y_{ts} = y_{xys} = y_{yxs} \qquad \text{(LL.130)}$$

$$y_{ti} = y_{xyi} = y_{yxi} \qquad \text{(LL.131)}$$

$$z_x = z_y = z_n = y_{ns} + y_{ni} \qquad \text{(LL.132)}$$

$$z_{xy} = z_{yx} = z_t = y_{ts} + y_{ti} \qquad \text{(LL.133)}$$

The difference between z_n and z_t may generally be ignored, assuming the thickness of the outer layers to be twice the concrete cover, therefore:

$$y_{ns} = y_{ts} = y_s \qquad \text{(LL.134)}$$

$$y_{ni} = y_{ti} = y_i \qquad \text{(LL.135)}$$

$$z_n = z_t = z \qquad \text{(LL.136)}$$

(114) Based on the above assumptions the forces in the outer layers can be evaluated as follows:

   a)   in the case for which no shear reinforcement is required to resist v_{Edx} and v_{Edy}

$$n_{Edxs} = n_{Edx} \frac{z - y_s}{z} + \frac{m_{Edx}}{z} \qquad \text{(LL.137)}$$

$$n_{Edxi} = n_{Edx} \frac{z - y_i}{z} - \frac{m_{Edx}}{z} \tag{LL.138}$$

$$n_{Edys} = n_{Edy} \frac{z - y_s}{z} + \frac{m_{Edy}}{z} \tag{LL.139}$$

$$n_{Edyi} = n_{Edy} \frac{z - y_i}{z} - \frac{m_{Edy}}{z} \tag{LL.140}$$

$$n_{Edxys} = n_{Edxy} \frac{z - y_s}{z} - \frac{m_{Edxy}}{z} \tag{LL.141}$$

$$n_{Edxyi} = n_{Edxy} \frac{z - y_i}{z} + \frac{m_{Edxy}}{z} \tag{LL.142}$$

b)   in the case for which shear reinforcement is required to resist v_{Edx} and v_{Edy}

$$n_{Edxs} = n_{Edx} \frac{z - y_s}{z} + \frac{m_{Edx}}{z} + \frac{1}{2} \frac{v_{Edx}^2}{v_{Edo}} \cot\theta \tag{LL.143}$$

$$n_{Edxi} = n_{Edx} \frac{z - y_i}{z} - \frac{m_{Edx}}{z} + \frac{1}{2} \frac{v_{Edx}^2}{v_{Edo}} \cot\theta \tag{LL.144}$$

$$n_{Edys} = n_{Edy} \frac{z - y_s}{z} + \frac{m_{Edy}}{z} + \frac{1}{2} \frac{v_{Edy}^2}{v_{Edo}} \cot\theta \tag{LL.145}$$

$$n_{Edyi} = n_{Edy} \frac{z - y_i}{z} - \frac{m_{Edy}}{z} + \frac{1}{2} \frac{v_{Edy}^2}{v_{Edo}} \cot\theta \tag{LL.146}$$

$$n_{Edxys} = n_{Edxy} \frac{z - y_s}{z} - \frac{m_{Edxy}}{z} + \frac{1}{2} \frac{v_{Edx} v_{Edy}}{v_{Edo}} \cot\theta \tag{LL.147}$$

$$v_{Edxyi} = n_{Edxy} \frac{z - y_i}{z} + \frac{m_{Edxy}}{z} + \frac{1}{2} \frac{v_{Edx} v_{Edy}}{v_{Edo}} \cot\theta \tag{LL.148}$$

(115) If the verification in (112) above is not satisfied, one of the following procedures should be followed:

a)   increase the concrete cover and consequently reduce the internal lever arm;
b)   use different values for z_n and z_t with $z_n > z_t$; internal concrete stresses should then be added vectorially;
c)   increase the layer thickness to satisfy the concrete verification and leave the reinforcement position unchanged. This will cause the reinforcement to become eccentric in the layer; as a consequence two internal bending moments arise, these should be in equilibrium within the shell element. In these circumstances, the internal forces in the reinforcement become:

$$n_{Eds}^* = \left[n_{Eds}\left(h - \frac{t_s}{2} - b_i'\right) + n_{Edi}\left(\frac{t_i}{2} - b_i'\right) \right] \Big/ \left(h - 2b_i'\right) \tag{LL.149}$$

$$n_{Edi}^* = n_{Eds} + n_{Edi} - n_{Eds}^* \tag{LL.150}$$

where:

- t_s and t_i are the thickness of top and bottom layers, respectively;
- b'_i is the distance from the external surface of the layer to the axis of the reinforcement within the layer.

The internal layer should be checked for an additional out of plane shear corresponding to the force transferred between the layers of reinforcement.

Annex MM (Informative)

Shear and transverse bending

(101) Within the webs of box girders the interaction between longitudinal shear and transverse bending may be considered by means of the sandwich model (see Annex LL). The following simplifications to the general model may be introduced for the purpose of this application (figure MM.1):

- The longitudinal shear per unit length should be considered as having a constant value along Δx : $v_{Ed} = V_{Ed} / \Delta x$.
- The transverse bending moment per unit length should be considered as having a constant value along Δy : $m_{Ed} = M_{Ed} / \Delta y$.
- The longitudinal force is assumed to have a constant value within the length Δy : $p_{Ed} = P_{Ed} / \Delta y$.
- The transverse shear within the web, due to variation in the corresponding bending moment, should be neglected within the length Δy .
Figure MM.1: Internal actions in a web element

(102) On the basis of the above assumptions, the sandwich model comprises only two plates in which the following stresses are acting (figure MM.2)

$$\tau_{Ed1} = v_{Ed} \frac{b_w - z_2}{(2b_w - z_1 - z_2)z_1} \tag{MM.101}$$

$$\tau_{Ed2} = v_{Ed} \frac{b_w - z_1}{(2b_w - z_1 - z_2)z_2} \tag{MM.102}$$

$$\sigma_{Edy1} = \frac{m_{Edx}}{\left(b_w - (z_1 + z_2)/2\right)z_1} \qquad \text{(MM.103)}$$

$$\sigma_{Edy2} = \frac{m_{Edx}}{\left(b_w - (z_1 + z_2)/2\right)z_2} \qquad \text{(MM.104)}$$

$$\sigma_{Edx1} = p_d \frac{b_w - z_2}{\left(2b_w - z_1 - z_2\right)z_1} \qquad \text{(MM.105)}$$

$$\sigma_{Edx2} = p_d \frac{b_w - z_1}{\left(2b_w - z_1 - z_2\right)z_2} \qquad \text{(MM.106)}$$
Figure MM.2: Modified sandwich model

(103) The design of two plates should be based on an iterative approach, in order to optimise the thickness z_1 and z_2 , using the procedure given in Section 6.109 and Annex F; different values for the θ_{el} angle and the θ angle may be assumed for the two plates, but they should have a constant value in each plate. If the resulting reinforcement is eccentric within the two plates, the expressions LL.149 and LL.150 of Annex LL should be applied.

(104) If the calculated longitudinal force is tensile, this may be carried by reinforcement distributed along the web or alternatively, may be considered to be transferred to the tensile and compression chords; half to the tensile chord and half to the compression chord.

(105) In the case of there being no longitudinal force, the rules of 6.24 rules may be used as a simplification, but the shear reinforcement should be added to the bending reinforcement.

Annex NN (informative)

Damage equivalent stresses for fatigue verification

NN.1. General

(101) This Appendix gives a simplified procedure for calculating the damage equivalent stresses for fatigue verification of superstructures of road and railway bridges of concrete construction. The procedure is based on the fatigue load models given in EN 1991-2.

NN.2. Road bridges

NN.2.1 Reinforcing and prestressing steel

(101) The values given in this subclause are only applicable to the modified fatigue load model 3 in EN 1991-2.
For the calculation of damage equivalent stress ranges for steel verification, the axle loads of fatigue load model 3 shall be multiplied by the following factors:
    1,75   for verification at intermediate supports in continuous bridges
    1,40   for verification in other areas

(102) The damage equivalent stress range for steel verification shall be calculated according to:

$$\Delta\sigma_{s,equ} = \Delta\sigma_{s,EC} \cdot \lambda_s \qquad \text{(NN.101)}$$

where:

$\Delta\sigma_{s,Ec}$ stress range caused by fatigue load model 3 (according to EN 1991-2) with the axle loads increased in accordance with (101), based on the load combination given in 6.8.3 of EN 1992-1-1.

λ_s damage equivalent factor for fatigue which takes account of site specific conditions including traffic volume on the bridge, design life and the span of the member.

(103) The correction factor λ_s, includes the influence of span, annual traffic volume, design life, multiple lanes, traffic type and surface roughness and can be calculated by

$$\lambda_s = \varphi_{fat} \cdot \lambda_{s,1} \cdot \lambda_{s,2} \cdot \lambda_{s,3} \cdot \lambda_{s,4} \qquad \text{(NN.102)}$$

where:

$\lambda_{s,1}$ is a factor accounting for element type (eg. continuous beam) and takes into account the damaging effect of traffic depending on the length of the influence line or area.

$\lambda_{s,2}$ is a factor that takes into account the traffic volume

$\lambda_{s,3}$ is a factor that takes into account the design life of the bridge

$\lambda_{s,4}$ is a factor to be applied when the structural element is loaded by more than one lane.

φ_{fat} damage equivalent impact factor controlled by the surface roughness.

(104)   The $\lambda_{s,1}$ value given in Figures NN.1 and NN.2 takes account of the length of the influence line and the shape of S-N-curve

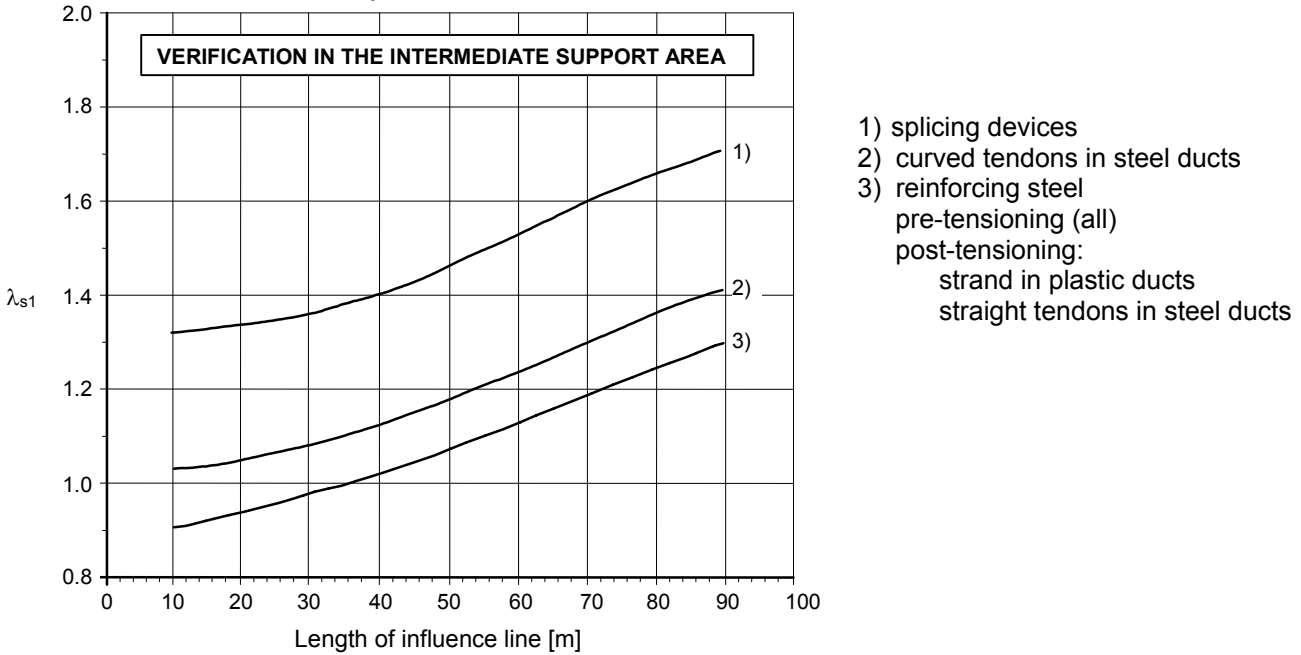

VERIFICATION IN THE INTERMEDIATE SUPPORT AREA

1) splicing devices
2) curved tendons in steel ducts
3) reinforcing steel
   pre-tensioning (all)
   post-tensioning:
      strand in plastic ducts
      straight tendons in steel ducts

Figure NN.1: $\lambda_{s,1}$ value for fatigue verification in the intermediate support area

VERIFICATION IN SPAN AND FOR CARRIAGEWAY SLAB

1) splicing devices
2) curved tendons in steel ducts
3) reinforcing steel
      pre-tensioning (all)
      post-tensioning:
         strand in plastic ducts
         straight tendons in steel ducts
4) shear reinforcement

a)   continuous beam
b)   single span beam
c)   carriageway slab
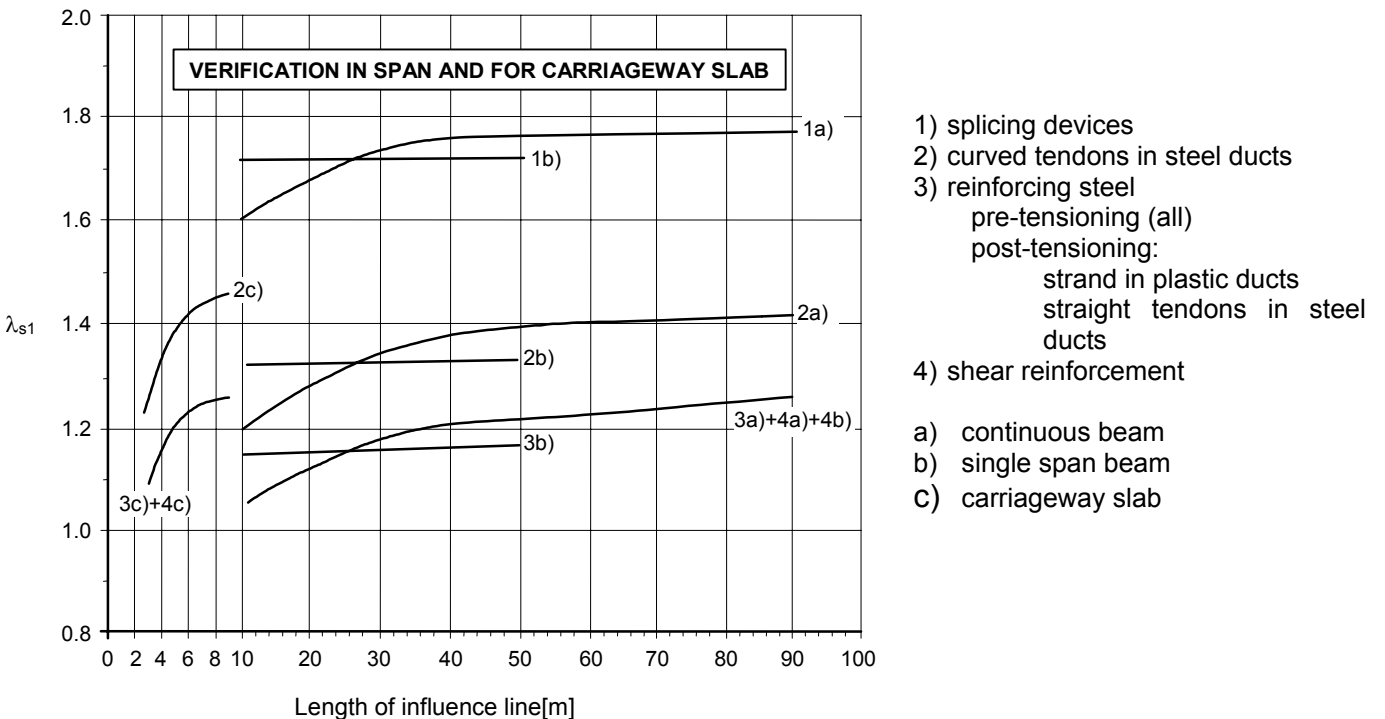

Figure NN.2: $\lambda_{s,1}$ value for fatigue verification in span and for local elements

(105)   The $\lambda_{s,2}$ value denotes the influence of the annual traffic volume and traffic type. It can be calculated by Equation (NN.103)

$$\lambda_{s,2} = \overline{Q}^{k_2} \sqrt{\frac{N_{obs}}{2.0}}$$ (NN.103)

where:

    N_{obs} number of lorries per year according to EN 1991-2, Table 4.5

    k_2 slope of the appropriate S-N-Line to be taken from Tables 6.3N and 6.4N of EN 1992-1-1

    $\overline{Q}$ factor for traffic type according to Table NN.1

Table NN.1 – Factors for traffic type

$\overline{Q}$ - factor for	Traffic type (see EN 1991-2 Table 4.7)		
	Long distance	Medium distance	Local traffic
$k_2 = 5$	1.0	0.90	0.73
$k_2 = 7$	1.0	0.92	0.78
$k_2 = 9$	1.0	0.94	0.82

(106) The $\lambda_{s,3}$ value denotes the influence of the service life and can be calculated from Equation (NN.104)

$$\lambda_{s,3} = \sqrt[k_2]{\frac{N_{Years}}{100}}$$ (NN.104)

where:

    N_{Years} design life of the bridge

(107) The $\lambda_{s,4}$ value denotes the influence for multiple lanes and can be calculated from Equation (NN.105)

$$\lambda_{s,4} = \sqrt[k_2]{\frac{\sum N_{obs,i}}{N_{obs,1}}}$$ (NN.105)

where:

    $N_{obs,i}$ number of lorries expected on lane i per year

    $N_{obs,1}$ number of lorries on the slow lane per year

(108) The φ_{fat} value is a damage equivalent impact factor according to EN 1991-2, Annex B

NN.3 Railway bridges

NN.3.1 Reinforcing and prestressing steel

(101) The damage equivalent stress range for reinforcing and prestressing steel shall be calculated according to Equation (NN.106)

$$\Delta\sigma_{s,equ} = \lambda_s \cdot \phi \cdot \Delta\sigma_{s,71}$$ (NN.106)

where:

    $\Delta\sigma_{s,71}$ steel stress range due to load model 71(and where required SW/0), but excluding

    α according to EN 1991.2, being placed in the most unfavourable position for the

element under consideration. For structures carrying multiple tracks, load model 71 shall be applied to a maximum of two tracks

λ_s correction factor to calculate the damage equivalent stress range from the stress range caused by $\phi \cdot \Delta\sigma_{s,71}$

ϕ dynamic factor according to EN 1991-2

(102) The correction factor λ_s, takes account of the span, annual traffic volume, design life and multiple tracks. It is calculated from the following formula:

$$\lambda_s = \lambda_{s,1} \cdot \lambda_{s,2} \cdot \lambda_{s,3} \cdot \lambda_{s,4} \tag{NN.107}$$

where:

$\lambda_{s,1}$ is a factor accounting for element type (eg. continuous beam) and takes into account the damaging effect of traffic depending on the length of the influence line or area.

$\lambda_{s,2}$ is a factor that takes into account the traffic volume.

$\lambda_{s,3}$ is a factor that takes into account the design life of the bridge

$\lambda_{s,4}$ is a factor to be applied when the structural element is loaded by more than one track.

(103) The factor $\lambda_{s,1}$ is a function of the length of the influence line and the traffic. The values of $\lambda_{s,1}$ for standard traffic mix and heavy traffic mix may be taken from Table NN.2 of this Annex. The values have been calculated on the basis of a constant ratio of bending moments to stress ranges. The values given for mixed traffic correspond to the combination of train types given in Annex F of EN 1991-2.

Values of $\lambda_{s,1}$ for a length of influence line between 2 m and 20 m may be obtained from the following equation:

$$\lambda_{s,1}(L) = \lambda_{s,1}(2m) + \left[\lambda_{s,1}(20m) - \lambda_{s,1}(2m)\right] \cdot (\log L - 0.3) \tag{NN.108}$$

where:

    L   is the length of the influence line in m

    $\lambda_{s,1}(2m)$ is the $\lambda_{s,1}$ value for L=2 m

    $\lambda_{s,1}(20m)$ is the $\lambda_{s,1}$ value for L=20 m

    $\lambda_{s,1}(L)$ is the $\lambda_{s,1}$ value for 2 m < L < 20 m

(104) The $\lambda_{s,2}$ value denotes the influence of annual traffic volume and can be calculated from Equation (NN.109)

$$\lambda_{s,2} = \sqrt[k_2]{\frac{Vol}{25 \cdot 10^6}} \tag{NN.109}$$

where:

    Vol   volume of traffic (tonnes/year/track)

    k_2 slope of appropriate S-N line to be taken from Tables 6.3N and 6.4N of EN 1992-1-1

(105) The $\lambda_{s,3}$ value denotes the influence of the service life and can be calculated from Equation (NN.110)

$$\lambda_{s,3} = \sqrt[k_2]{\frac{N_{Years}}{100}}$$ (NN.110)

where:

    N_{Years} design life of the bridge

    k_2 slope of appropriate S-N line to be taken from Tables 6.3N and 6.4N of EN 1992-1-1

(106) The $\lambda_{s,4}$ value denotes the effect of loading from more than one track. For structures carrying multiple tracks, the fatigue loading shall be applied to a maximum of two tracks in the most unfavourable positions (see EN 1991-2). The effect of loading from two tracks can be calculated from Equation(NN.111).

$$\lambda_{s,4} = \sqrt[k_2]{n + (1-n) \cdot s_1^{k_2} + (1-n) \cdot s_2^{k_2}}$$ (NN.111)

$$s_1 = \frac{\Delta\sigma_1}{\Delta\sigma_{1+2}} \qquad\qquad s_2 = \frac{\Delta\sigma_2}{\Delta\sigma_{1+2}}$$

where:

    n proportion of traffic that crosses the bridge simultaneously (the suggested value of n is 0,12)

    $\Delta\sigma_1$, $\Delta\sigma_2$ stress range due to load model 71 on one track at the section to be checked

    $\Delta\sigma_{1+2}$ stress range at the same section due to the load model 71 on any two tracks, according to EN 1991-2

    k_2 slope of appropriate S-N line to be taken from Tables 6.3N and 6.4N of EN 1992-1-1

If only compressive stresses occur under traffic loads on a track, set the corresponding value $s_j=0$

Table NN.2. $\lambda_{s,1}$ **values for simply supported and continuous beams**

s*   standard traffic mix
h*   heavy traffic mix
[1]   reinforcing steel, pre-tensioning (all), post-tensioning (strands in plastic ducts and straight tendons in steel ducts)
[2]   post-tensioning (curved tendons in steel ducts); S-N curve with $k_1=3$, $k_2=7$ and $N^*=10^6$
[3]   splice devices (prestressing steel); S-N curve with $k_1=3$, $k_2=5$ and $N^*=10^6$
[4]   splice devices (reinforcing steel); welded bars including tack welding and butt joints; S-N curve with $k_1=3$, $k_2=5$ and $N^*=10^7$
Interpolation between the given L-values according to Equation NN.103 is allowed

Note: No values of $\lambda_{s,1}$ are given in Table NN2 for a light traffic mix. For bridges designed to carry a light traffic mix the values for $\lambda_{s,1}$ to be used may be based either on the values given in Table NN2 for standard traffic mix or on values determined from detailed calculations.

NN.3.2 Concrete subjected to compression

(101) For concrete subjected to compression adequate fatigue resistance may be assumed if the following expression is satisfied:

$$14 \cdot \frac{1 - E_{cd,max,equ}}{\sqrt{1 - R_{equ}}} \geq 6$$
(NN.112)

where:

$$R_{equ} = \frac{E_{cd,min,equ}}{E_{cd,max,equ}} \qquad E_{cd,min,equ} = \gamma_{sd} \frac{\sigma_{cd,min,equ}}{f_{cd,fat}} \qquad E_{cd,max,equ} = \gamma_{sd} \frac{\sigma_{cd,max,equ}}{f_{cd,fat}}$$

$\sigma_{cd,\max,equ}$ and $\sigma_{cd,\min,equ}$ are the upper and lower stresses of the damage equivalent stress spectrum with a number of cycles $N=10^6$

(102) The upper and lower stresses of the damage equivalent stress spectrum shall be calculated according to Equation (NN.113)

$$\sigma_{cd,max,equ} = \sigma_{c,perm} + \lambda_c \left(\sigma_{c,max,71} - \sigma_{c,perm} \right)$$
$$\sigma_{cd,min,equ} = \sigma_{c,perm} - \lambda_c \left(\sigma_{c,perm} - \sigma_{c,min,71} \right)$$
(NN.113)

where:

$\sigma_{c,perm}$ compressive concrete stress caused by the characteristic combination of actions, without load model 71.

$\sigma_{c,max,71}$ maximum compressive stress caused by the characteristic combination including load model 71 and the dynamic factor ϕ according to EN 1991-2.

$\sigma_{c,min,71}$ minimum compressive stress under the characteristic combination including load model 71 and the dynamic factor ϕ according to EN 1991-2.

λ_c correction factor to calculate the upper and lower stresses of the damage equivalent stress spectrum from the stresses caused by load model 71.

Note: $\sigma_{c,perm}$, $\sigma_{c,max,71}$ and $\sigma_{c,min,71}$ do not include other variable actions (eg. wind, temperature etc.).

(103) The correction factor λ_c takes account of the permanent stress, the span, annual traffic volume, design life and multiple tracks. It is calculated from the following formula:

$$\lambda_c = \lambda_{c,0} \cdot \lambda_{c,1} \cdot \lambda_{c,2,3} \cdot \lambda_{c,4} \qquad\qquad\qquad \text{(NN.114)}$$

where:

   $\lambda_{c,0}$ factor to take account of the permanent stress.

   $\lambda_{c,1}$ factor accounting for element type (eg. continuous beam) that takes into account the damaging effect of traffic depending on the length of the influence line or area.

   $\lambda_{c,2,3}$ factor to take account of the traffic volume and the design life of the bridge.

   $\lambda_{c,4}$ factor to be applied when the structural element is loaded by more than one track.

(104) The $\lambda_{c,0}$ value denotes the influence of the permanent stress and can be calculated from Equation (NN.115)

$$\lambda_{c,0} = 0.94 + 0,2\frac{\sigma_{c,perm}}{f_{cd,fat}} \geq 1 \qquad\qquad \text{for the compression zone} \qquad\qquad \text{(NN.115)}$$

$$\lambda_{c,0} = 1 \qquad\qquad\qquad\qquad\qquad \text{for the precompressed tensile zone}$$

(105) The factor $\lambda_{c,1}$ is a function of the length of the influence line and the traffic. The values of $\lambda_{c,1}$ for standard traffic mix and heavy traffic mix may be taken from Table NN.2 of this Annex. Values of $\lambda_{c,1}$ for spans between 2 m and 20 m may be obtained by applying Equation (NN.103) with $\lambda_{s,1}$ replaced by $\lambda_{c,1}$.

(106) The $\lambda_{c,2,3}$ value denotes the influence of annual traffic volume and service life and can be calculated from Equation (NN.116)

$$\lambda_{c,2,3} = 1 + \frac{1}{8}log\left[\frac{Vol}{25 \cdot 10^6}\right] + \frac{1}{8}log\left[\frac{N_{Years}}{100}\right] \qquad\qquad \text{(NN.116)}$$

where:

   Vol   volume of traffic (tonnes/years/track)
   N_{Years} design life of the bridge

(107)   The $\lambda_{c,4}$ value denotes the effect of loading from more than one track. For structures carrying multiple tracks, the fatigue loading shall be applied to a maximum of two tracks in the most unfavourable positions (see EN 1991-2). The effect of loading from two tracks may be calculated from Equation (NN.117)

$$\lambda_{c,4} = 1 + \frac{1}{8} \log n \geq 0.54 \qquad \text{for a} \leq 0.8 \qquad (NN.117)$$

$$\lambda_{c,4} = 1 \qquad \text{for a} > 0.8$$

$$a = \frac{max(\sigma_{c1}, \sigma_{c2})}{\sigma_{c1+2}} \qquad (NN.118)$$

where:

 n   proportion of traffic crossing the bridge simultaneously (the recommended value of n is 0,12).

σ_{c1}, σ_{c2} compressive stress caused by load model 71 on one track, including the dynamic factor for load model 71 according to EN 1991-2

σ_{c1+2} compressive stress caused by load model 71 on two tracks, including the dynamic factor for load model 71 according to EN 1991-2

Table NN.3. $\lambda_{c,1}$ values for simply supported and continuous beams

	L [m]	s*	h*
[1]	≤2	0.70	0.70
	≥20	0.75	0.75
[2]	≤2	0.95	1.00
	≥20	0.90	0.90

Simply supported beams

	L [m]	s*	h*
[1]	≤2	0.75	0.90
	≥20	0.55	0.55
[2]	≤2	1.05	1.15
	≥20	0.65	0.70

Continuous beams (mid span)

	L [m]	s*	h*
[1]	≤2	0.75	0.80
	≥20	0.70	0.70
[2]	≤2	1.10	1.20
	≥20	0.70	0.70

Continuous beams (end span)

	L [m]	s*	h*
[1]	≤2	0.70	0.75
	≥20	0.85	0.85
[2]	≤2	1.10	1.15
	≥20	0.80	0.85

Continuous beams
(intermediate support area)

 s*   standard traffic mix
 h*   heavy traffic mix
 [1]   compression zone
 [2]   precompressed tensile zone
 Interpolation between the given L-values according to Equation NN.103 is allowed, with $\lambda_{s,1}$ replaced by $\lambda_{c,1}$.

Note: No values of $\lambda_{c,1}$ are given in Table NN3 for a light traffic mix. For bridges designed to carry a light traffic mix the values for $\lambda_{c,1}$ to be used may be based either on the values given in Table NN3 for standard traffic mix or on values derived from detailed calculations.

ANNEX OO (Informative)

Typical bridge discontinuity regions

OO.1 Diaphragms with direct support of box section deck webs on bearings

(101) Diaphragms where the bearings are located directly below the webs of the box section will be subject to forces generated by the transmission of shear in the horizontal plane (Figure OO.1), or forces due to the transformation of the torsional moment in the deck into a pair of forces in cases where two bearings are present (Figure OO.2).
Figure OO.1: Horizontal shear and reactions in bearings
Figure OO.2: Torsion in the deck and reactions in bearings

(102) In general, from Figures OO.1 and OO.2 it can be seen that the flow of the forces from the lower flange and from the webs is channelled directly to the supports without any forces being induced in the central part of the diaphragm. The forces from the upper flange result in forces being applied to the diaphragm and these determine the design of the element. Figures OO.3 and OO.4 identify possible resistance mechanisms that can be used to determine the necessary reinforcement t for elements of this type.
Figure OO.3: Strut and tie model for a solid type diaphragm without manhole..
Figure OO.4: Strut and tie model for a solid type diaphragm with manhole.

(103) Generally, it is not necessary to check nodes or struts when the thickness of the diaphragm is equal to or greater than the dimension of the support area in the longitudinal direction of the bridge. In these circumstances, it is then only necessary to check the support nodes.

OO.2 Diaphragms for indirect support of deck webs on bearings.

(101) In this case, in addition to the shear along the horizontal axis and, in the case of more than one support, the effect of the torsion, the diaphragm must transmit the vertical shear forces, transferred from the webs, to the bearing or bearings.
The nodes at the bearings must be checked using the criteria given in 6.5 and 6.7 of EN 1992-1-1.
Figure OO.5: Diaphragms with indirect support. Strut and tie model.

(102) Reinforcement should be designed for the tie forces obtained from the resistance mechanisms adopted, taking account of limitations on tension in the reinforcement indicated in 6.5 of EN 1992-1-1. In general, due to the way in which vertical shear is transmitted, it will be necessary to provide suspension reinforcement. If inclined bars are used for this, special attention should be paid to the anchorage conditions (Figure OO.6).
Figure OO.6: Diaphragms with indirect support. Anchorage of the suspension reinforcement.

(103) If the suspension reinforcement is provided in the form of closed stirrups, these must enclose the reinforcement in the upper face of the box girder (Figure OO.7).
Figure OO.7: Diaphragms with indirect support. Links as suspension reinforcement.

(104) In cases where prestressing is used, such as post - tensioned tendons, the design will clearly define the order in which these have to be tensioned (diaphragm prestressing should

generally be carried out before longitudinal prestressing). Special attention should be paid to the losses in the prestressing, given the short length of the tendons.

(105) In addition to the reinforcement obtained on the basis of the resistance mechanisms identified above, it will be necessary to have the load reinforcement concentrated on the area located on the supports.

OO.3 Diaphragms in monolithic deck-pier joints

(101) In cases where the deck and pier are monolithic, the difference in deck moments in adjacent spans on either side of the pier must be transmitted to the pier. This moment transmission will generate additional forces to those identified in the previous clauses.

(102) In the case of triangular diaphragms (Figure OO.8), transmission of the vertical load and the force caused by the difference in moments is direct, as long as the continuity of the compression struts and overlapping (or anchorage) of the tension reinforcement is provided.

(103) In the case of a double vertical diaphragm, the flow of forces from the deck to the piers is more complex. In this case, it is necessary to carefully check the continuity of the compression flow.
Figure OO.8: Diaphragm in monolithic joint with double diaphragm:

Equivalent system of struts and ties.

OO.4 Diaphragms in decks with double T sections and bearings under the webs

(101) In this case, the diaphragms will be subject to forces generated by the transmission of shear in the horizontal axis (Figure OO.9), or forces due to the transformation of the torsional moment in the deck into a pair of forces in the case where two supports are present(Figure OO.10).

(102) In general, from Figures OO.9 and OO.10, it can be seen that the flow of forces from the webs is channelled directly at the supports without any forces being induced in the central part of the diaphragm. The forces from the upper flange result in forces being applied to the diaphragm and these have to be considered in the design.
**Figure OO.9: Horizontal shear and reactions in supports**

Figure OO.10: Torsion in the deck slab and reactions in the supports

Figure OO.11 shows a possible resistance mechanism that enables the required reinforcement to be determined.

In general, if the thickness of the diaphragm is equal to or greater than the dimension of the bearing area in the longitudinal direction of the bridge, it will only be necessary to check the support nodes in accordance with 6.5 of EN 1992-1-1.
Figures OO.11: Model of struts and ties for a typical diaphragm of a slab

ANNEX PP (Informative)

Safety format for non linear analysis

PP.1 Practical application

(101) For the case of scalar combination of internal actions, reverse application of inequalities 5.102a and 5.102b is shown diagramatically in Figures PP.1 and PP.2, for underproportional and overproportional structural behaviour respectively.

**Figure PP.1: Safety format application for scalar underproportional behaviour**

Figure PP.2: Safety format application for scalar overproportional behaviour

(102) For the case of vectorial combination of internal actions, the application of inequalities 5.102 a and b is illustrated in Figures PP.3 and PP.4, for underproportional and overproportional structural behaviour respectively. Curve a represents the failure line, curve b is obtained by scaling this line by applying safety factors γ_{Rd} and γ_o.

**Figure PP.3: Safety format application for vectorial (M,N) underproportional behaviour**

Figure PP.4: Safety format application for vectorial (M,N) overproportional behaviour

In both figures, D represents the intersection between the internal actions path and the safety domain "b".
It should be verified that the point with coordinates

$$M\left(\gamma_G G + \gamma_Q Q\right) \qquad \text{and} \qquad N\left(\gamma_G G + \gamma_Q Q\right)$$

i.e. the point corresponding to the internal actions (the effects of factored actions), should remain within the safety domain "b".

An equivalent procedure applies where the partial factor for model uncertainty γ_{Sd} is introduced, but with γ_{Rd} substituted by $\gamma_{Rd}\gamma_{Sd}$ and γ_G, γ_Q substituted by γ_g, γ_q.

The same procedures applies for the combination of N/M$_x$/M$_y$ or n$_x$/n$_y$/n$_{xy}$.

Note: If the procedure with $\gamma_{Rd} = \gamma_{Sd} = 1$ and $\gamma_{O'} = 1{,}27$ is applied, the safety check is satisfied if M$_{Ed} \le$ M$_{Rd}$ (q$_{ud}$/γ$_{O'}$) and N$_{Ed} \le$ N$_{Rd}$ (q$_{ud}$/γ$_{O'}$).

ANNEX QQ (Informative) Control of shear cracks within webs

At present, the prediction of shear cracking in webs is accompanied by large model uncertainty.

Where it is considered necessary to check shear cracking, particularly for prestressed members, the reinforcement required for crack control can be determined as follows:

1. The directionally dependent concrete tensile strength f_{ctb} within the webs should be calculated from:

$$f_{ctb} = \left(1 - 0.8\frac{\sigma_3}{f_{ck}}\right)f_{ctk;0,05}$$ (QQ.101)

where:

f_{ctb} is the concrete tensile strength prior to cracking in a biaxial state of stress

σ_3 is the minimum principal stress.

       $\sigma_3 < 0.6\ f_{ck}$

2. The maximum principal stress σ_1 in the web is compared with the corresponding strength f_{ctb} obtained from expression (QQ 104).

If $\sigma_1 < f_{ctb}$, the minimum reinforcement in accordance with 7.3.2 should be provided in the longitudinal direction.

If $\sigma_1 \geq f_{ctb}$, the crack width should be controlled in accordance with 7.3.3 or alternatively calculated and verified in accordance with 7.3.4 and 7.3.1, taking into account the angle of deviation between the principal stress and reinforcement directions.

EUROPEAN STANDARD

NORME EUROPÉENNE

EUROPÄISCHE NORM

FINAL DRAFT

prEN 1992-3

July 2005

Will supersede ENV 1992-4:1998

English Version

Eurocode 2 - Design of concrete structures - Part 3: Liquid retaining and containment structures

Eurocode 2 - Calcul des structures en béton - Partie 3: Silos et réservoirs

Eurocode 2 - Bemessung und Konstruktion von Stahlbeton- und Spannbetontragwerken - Teil 3: Stütz- und Behälterbauwerke aus Beton

This draft European Standard is submitted to CEN members for formal vote. It has been drawn up by the Technical Committee CEN/TC 250.

If this draft becomes a European Standard, CEN members are bound to comply with the CEN/CENELEC Internal Regulations which stipulate the conditions for giving this European Standard the status of a national standard without any alteration.

This draft European Standard was established by CEN in three official versions (English, French, German). A version in any other language made by translation under the responsibility of a CEN member into its own language and notified to the Management Centre has the same status as the official versions.

CEN members are the national standards bodies of Austria, Belgium, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden, Switzerland and United Kingdom.

Warning : This document is not a European Standard. It is distributed for review and comments. It is subject to change without notice and shall not be referred to as a European Standard.

Foreword

This document (prEN 1992-3:2005) has been prepared by Technical Committee CEN/TC 250 "Structural Eurocodes", the secretariat of which is held by BSI.

This document is currently submitted to the Formal Vote.

This document has been prepared under a mandate given to CEN by the European Commission and the European Free Trade Association, and supports essential requirements of EU Directive(s).

For relationship with EU Directive(s), see informative Annex ZA, B, C or D, which is an integral part of this document.

This document (prEN 1992-3:2005) has been prepared by Technical Committee CEN/TC 250 "Structural Eurocodes", the secretariat of which is held by BSI.

This Eurocode supersedes ENV 1992-4.

Background of the Eurocode programme

See EN 1992-1-1.

Eurocode programme

See EN 1992-1-1.

Status and Field of application of Eurocodes

See EN 1992-1-1.

National Standards implementing Eurcodes

See EN 1992-1-1.

Links between Eurocodes and harmonized technical specifications (ENs and ETAs) for products

See EN 1992-1-1.

Additional information specific to EN 1992-3 and link to EN 1992-1-1

The scope of Eurocode 2 is defined in 1.1.1 of EN 1992-1-1 and the scope of this Part of Eurocode 2 is defined in 1.1.2. Other Additional Parts of Eurocode 2 which are planned are indicated in 1.1.3 of EN 1992-1-1; these will cover additional technologies or applications, and will complement and supplement this Part. It has been necessary to introduce into EN 1992-3 a few clauses which are not specific to liquid retaining or containment structures and which strictly belong to Part 1-1. These are deemed valid interpretations of Part 1-

1 and design complying with the requirements of EN 1992-3 are deemed to comply with the principles of EN 1992-1-1.

It should be noted that any product, such as concrete pipes, which are manufactured and used in accordance with a product standard for a watertight product, will be deemed to satisfy the requirements of this code without further calculation.

There are specific regulations for the surfaces of storage structures which are designed to contain foodstuffs or potable water. These should be referred to as necessary and their provisions are not covered in this code.

In using this document in practice, particular regard should be paid to the underlying assumptions and conditions given in 1.3 of EN 1992-1-1.

The five chapters of this document are complemented by five Informative Annexes. These Annexes have been introduced to provide general information on material and structural behaviour which may be used in the absence of information specifically related to the actual materials used or actual conditions of service.

As indicated above, reference should be made to National annexes which will give details of compatible supporting standards to be used. For this Part of Eurocode 2, particular attention is drawn to EN 206 (Concrete - performance, production, placing and compliance criteria).

For EN 1992-3, the following additional sub-clauses apply.

This Part 3 of Eurocode 2 complements EN 1992-1-1 for the particular aspects of liquid retaining structures and structures for the containment of granular solids.

The framework and structure of this Part 3 correspond to EN 1992-1-1. However, Part 3 contains Principles and Application Rules which are specific to liquid retaining and containment structures.

Where a particular sub-clause of EN 1992-1-1 is not mentioned in this EN 1992-3, that sub-clause of EN 1992-1-1 applies as far as deemed appropriate in each case.

Some Principles and Application Rules of EN 1992-1-1 are modified or replaced in this Part, in which case the modified versions supersede those in EN 1992-1-1 for the design of liquid retaining or containment structures.

Where a Principle or Application Rule in EN 1992-1-1 is modified or replaced, the new number is identified by the addition of 100 to the original number. Where a new Principle or Application Rule is added, it is identified by a number which follows the last number in the appropriate clause in EN 1992-1-1 with 100 added to it.

A subject not covered by EN 1992-1-1 is introduced in this Part by a new sub-clause. The sub-clause number for this follows the most appropriate clause number in EN 1992-1-1.

The numbering of equations, figures, footnotes and tables in this Part follow the same principles as the clause numbering as described above.

National annex for EN 1992-3

This standard gives values with notes indicating where national choices may have to be made. Therefore the national Standard implementing EN 1992-3 should have a National annex containing all Nationally Determined Parameters to be used for the design of liquid retaining and containment structures to be constructed in the relevant country.

National choice is allowed in EN 1992-3 through the following clauses:

7.3.1 (111)
7.3.1 (112)
7.3.3

8.10.3.3 (102) and (103)

9.11.1 (102)

Section 1 General

1.1 Scope

Replacement of clause 1.1.2 in EN 1992-1-1 by:

1.1.2   Scope of Part 3 of Eurocode 2

(101)P   Part 3 of EN 1992 covers additional rules to those in Part 1 for the design of structures constructed from plain or lightly reinforced concrete, reinforced concrete or prestressed concrete for the containment of liquids or granular solids.

(102)P   Principles and Application Rules are given in this Part for the design of those elements of structure which directly support the stored liquids or materials (i.e. the directly loaded walls of tanks, reservoirs or silos). Other elements which support these primary elements (for example, the tower structure which supports the tank in a water tower) should be designed according to the provisions of Part 1-1.

(103)P   This part does not cover:

⎯ Structures for the storage of materials at very low or very high temperatures

⎯ Structures for the storage of hazardous materials the leakage of which could constitute a major health or safety risk.

⎯ The selection and design of liners or coatings and the consequences of the choice of these on the design of the structure.

⎯ Pressurised vessels.

⎯ Floating structures

⎯ Gas tightness

(104)   This code is valid for stored materials which are permanently at a temperature between $-40\,°C$ and $+200\,°C$.

(105)   For the selection and design of liners or coatings, reference should be made to appropriate documents.

(106)   It is recognised that, while this code is specifically concerned with structures for the containment of liquids and granular materials, the clauses covering design for liquid tightness may also be relevant to other types of structure where liquid tightness is required.

(107)   In clauses relating to leakage and durability, this code mainly covers aqueous liquids. Where other liquids are stored in direct contact with structural concrete, reference should be made to specialist literature.

1.2 Normative references

The following normative documents contain provisions that, though referenced in this text, constitute provisions of this European Standard. For dated references, subsequent amendments to, or revisions of, any of these publications do not apply. However, parties to agreements based on this European Standard are encouraged to investigate the possibility of applying the most recent editions of the normative documents indicated below. For undated references, the latest edition of the normative document referred to applies.

EN 1990, Eurocode, *Basis of structural design*

EN 1991-1-5, Eurocode 1, *Actions on structures – Part 1-5: General Actions – Thermal actions*

EN 1991-4, Eurocode 1, *Actions on structures – Part 4: Silos and tanks*

EN 1992-1-1, Eurocode 2, *Design of concrete structures – Part 1.1: General rules and rules for buildings*

EN 1992-1-2, Eurocode 2, *Design of concrete structures – Part 1.2: General rules – Structural fire design*

EN 1997, Eurocode 7: *Geotechnical design*

1.6   Symbols

Addition after 1.6

1.7   Special symbols used in Part 3 of Eurocode 2

Latin upper case symbols

R_{ax} factor defining the degree of external axial restraint provided by elements attached to the element considered

R_m factor defining the degree of moment restraint provided by elements attached to the element considered.

Latin lower case symbols

f_{ctx} tensile strength, however defined

f_{ckT} characteristic compressive strength of the concrete modified to take account of temperature.

Greek symbols

ε_{av} average strain in the element

ε_{az} actual strain at level z

ε_{iz} imposed intrinsic strain at level z

ε_{Tr} transitional thermal strain

ε_{Th} free thermal strain in the concrete

Section 2   Basis of design

1.3 Requirements

1.3.1   Basic requirements

Addition following (3):

(104)   The design situations to be considered should comply with EN 1990, EN 1991-4 and EN 1991-1-5, chapter 3. In addition, for liquid retaining and containment structures made with concrete, the following special design situations may be relevant:

—   Operating conditions implying patterns of discharge and filling;

—   Dust explosions;

— Thermal effects caused, for example, by stored materials or environmental temperature;

— Requirements for testing of reservoirs for watertightness.

2.3 Basic variables

2.3.1 Actions and environmental influences

2.3.1.1 General

Add to this sub-clause:

(102)P   The partial safety factors for the actions for liquid retaining and containment structures are set out in Normative Annex B of EN 1991-4.

(103)   Actions resulting from soil or water within the ground should be obtained in accordance with EN 1997.

2.3.2 Material and product properties

2.3.2.3 Properties of concrete with respect to watertightness

(101)   If the minimum thicknesses of the member given in 9.11 (102) are used then a lower water-cement ratio may be required and, consideration should be given to a limitation to the maximum aggregate size.

Section 3 Materials

1.4 Concrete

1.4.1 General

(103)   Information on the effect of temperature on the properties of concrete is given in informative Annex K.

3.1.3 Elastic deformation

replace (5) by:

(105)   Unless more accurate information is available, the linear coefficient of thermal expansion may be taken as equal to $10 \times 10^{-6} K^{-1}$. It should be noted, however, that coefficients of thermal expansion of concrete vary considerably depending on the aggregate type and the moisture conditions within the concrete.

3.1.4 Creep and Shrinkage

Addition after application rule (5)

(106)   Where the elements are exposed for substantial periods to high temperature (> 50 °C), creep behaviour is substantially modified. Where this is likely to be significant, appropriate data should generally be obtained for the particular conditions of service envisaged. Guidance is given in Informative Annex K on the estimation of creep effects at elevated temperatures.

3.1.11 Heat evolution and temperature development due to hydration

(101)   Where conditions during the construction phase are considered to be significant, the heat evolution characteristics for a particular cement should generally be obtained from tests. The actual heat evolution should be determined taking account of the expected conditions during the early life of the member (eg curing,

ambient conditions). The maximum temperature rise and the time of occurrence after casting should be established from the mix design, the nature of the formwork, the ambient conditions and the boundary conditions.

1.5 Reinforcing steel

3.2.2 Properties

(107)   For reinforcing steel subjected to temperatures in the range -40 to +100 °C (if no special investigation is made) reference should be made to 1992-1-1, clause 10.3.2.2. For higher temperature, information may be found in 3.2.3 of EN 1992-1-2.

1.6 Prestressing steel

3.3.2 Properties

(110)   For prestressing strands subjected to temperatures in the range -40 to +100 °C (if no special investigation is made) the same values for strength and relaxation apply as for "normal temperatures". For higher temperatures, information may be found in 3.2.4 of EN 1992-1-2.

Section 4 Durability and cover to reinforcement

1.7 Durability requirements

Addition after 4.4.1.2 (13)

(114)   Abrasion of the inner face of the walls of a silo may cause contamination of the stored material or lead to significant loss of cover. Three mechanisms of abrasion may occur:

⸺ mechanical attack due to the filling and discharging process.

⸺ physical attack due to erosion and corrosion with changing temperature and moisture conditions.

⸺ chemical attack due to reaction between the concrete and the stored material.

(115)   Appropriate measures should be taken to ensure that the elements subject to abrasion will remain serviceable for the design working life.

Section 5 Structural analysis

Addition after 5.11

5.12 Determination of the effects of temperature

5.12.1 General

(101)   Rigorous analyses may be carried out using the provisions of 3.1.4 and Annex B of EN 1992-1-1 for creep and shrinkage.

(102)   In storage structures, high temperature gradients may occur where the stored material is either self heating or is put into the structure at high temperature. In such circumstances calculation of the resulting temperature gradients and the consequent internal forces and moments will be necessary.

5.13 Calculation of the effects of internal pressure

(101)   The internal pressure from solid materials acts directly upon the inner surface of the concrete. In the absence of a more rigorous analysis, internal pressure from liquids may be assumed to act at the centre of the retaining members.

Section 6 Ultimate limit states

Addition after 6.2.3 (8)

(109)   The choice of strut angle in 6.3.2(2) for shear resistance should take into account the influence of any significant applied tension. Conservatively, $\cot\theta$ may be taken as 1.0. The procedure in Annex QQ of EN1992-2 may also be used.

Addition after 6.8

6.9   Design for dust explosions

6.9.1   General

(101)P   Where silos are designed to contain materials which may pose a risk of dust explosions, the structure shall either be designed to withstand the resulting expected maximum pressures or be provided with suitable venting which will reduce the pressure to a supportable level. The appropriate loads resulting from dust explosions are dealt with in EN 1991-4 and general considerations relating to design for explosions in 1991-1-7 however, the points in 6.9.2 (101) to (105) should be noted.

(102)P   Fire expelled through a venting outlet shall not cause any impairment of the surroundings nor cause explosions in other sections of the silo. Risks to people due to flying glass or other debris shall be minimised.

(103)   Vent openings should lead directly to open air through planned venting outlets, which reduce the explosion pressure.

(104)   Venting systems should be initiated at low pressure and have low inertia.

(105)   Actions due to dust explosions should be treated as accidental actions.

6.9.2   Design of structural elements

(101)   The maximum pressures due to explosions occur in empty silo bins, however, the pressures in a partly filled silo bin combined with the corresponding pressures from the bulk material may lead to a more critical design condition.

(102)   When inertia forces arise due to a rapid discharge of gas followed by cooling of the hot smoke, a pressure below atmospheric may occur. This should be taken into account when designing the encasing structure and members in the flow path.

(103)   The elements forming a venting device should be secured against flying off and adding to the risks from flying debris.

(104)   As pressure relief due to venting occurs, reaction forces are generated which should be taken into account in the design of structural members.

(105)   Specialist assistance should be sought where complex installations are contemplated or where explosions might pose a high risk of injury.

Section 7 Serviceability limit states

7.3 Cracking

7.3.1 General considerations

Addition after (9)P

(110)   It is convenient to classify liquid retaining structures in relation to the degree of protection against leakage required. Table 7.105 gives the classification. It should be noted that all concrete will permit the passage of small quantities of liquids and gasses by diffusion.

Table 7.105 — Classification of tightness

Tightness Class	Requirements for leakage
0	Some degree of leakage acceptable, or leakage of liquids irrelevant.
1	Leakage to be limited to a small amount. Some surface staining or damp patches acceptable.
2	Leakage to be minimal. Appearance not to be impaired by staining.
3	No leakage permitted

(111)   Appropriate limits to cracking depending on the classification of the element considered should be selected, paying due regard to the required function of the structure. In the absence of more specific requirements, the following may be adopted.

Tightness Class 0. —   the provisions in 7.3.1 of EN 1992-1-1 may be adopted.

Tightness Class 1. —   any cracks which can be expected to pass through the full thickness of the section should be limited to w_{k1}. The provisions in 7.3.1 of EN 1992-1-1 apply where the full thickness of the section is not cracked and where the conditions in (112) and (113) below are fulfilled.

Tightness Class 2. —   cracks which may be expected to pass through the full thickness of the section should generally be avoided unless appropriate measures (e.g. liners or water bars) have been incorporated.

Tightness Class 3. —   generally, special measures (e.g. liners or prestress) will be required to ensure watertightness.

NOTE   The value of w_{k1} for use in a country may be found in its National Annex. The recommended values for structures retaining water are defined as a function of the ratio of the hydrostatic pressure, h_D to the wall thickness of the containing structure, h. For $h_D/h \leq 5$, $w_{k1} = 0.2$ mm while for $h_D/h \geq 35$, $w_{k1} = 0.05$ mm. For intermediate values of h_D/h, linear interpolation between 0.2 and 0.05 may be used. Limitation of the crack widths to these values should result in the effective sealing of the cracks within a relatively short time.

(112)   To provide adequate assurance for structures of classes 2 or 3 that cracks do not pass through the full width of a section, the design value of the depth of the compression zone should be at least x_{min} calculated for the quasi-permanent combination of actions. Where a section is subjected to alternate actions, cracks should be considered to pass through the full thickness of the section unless it can be shown that some part of the section thickness will always remain in compression. This thickness of concrete in compression should normally be at least x_{min} under all appropriate combinations of actions. The action effects may be calculated on the assumption of linear elastic material behaviour. The resulting stresses in a section should be calculated assuming that concrete in tension is neglected

NOTE   The values of x_min for use in a country may be found in its National Annex. The recommended value for x_min is the lesser of 50 mm or 0.2h where h is the element thickness.

(113)   If the provisions of 7.3.1 (111) for tightness class 1 are met then cracks through which water flows may be expected to heal in members which are not subjected to significant changes of loading or temperature during service. In the absence of more reliable information, healing may be assumed where the expected range of strain at a section under service conditions is less than 150×10^{-6}.

(114)   If self-healing is unlikely to occur, any crack which passes through the full thickness of the section may lead to leakage, regardless of the crack width.

(115)   Silos holding dry materials may generally be designed as Class 0 however it may be appropriate for Class 1, 2 or 3 to be used where the stored material is particularly sensitive to moisture.

(116)   Special care should be taken where members are subject to tensile stresses due to the restraint of shrinkage or thermal movements.

(117)   Acceptance criteria for liquid retaining structures may include maximum level of leakage.

7.3.3   Control of cracking without direct calculation

Replace note in Application Rule (2):

NOTE   Where the minimum reinforcement given by 7.3.2 is provided, Figures 7.103N and 7.104N give values of maximum bar diameters and bar spacings for various design crack widths for sections totally in tension.

The maximum bar diameter given by Figure 7.103N should be modified using Expression 7.122 below rather than Expression 7.7 which applies where ϕ_s^* has been calculated for pure flexure:

$$\phi_s = \phi_s^* \left(\frac{f_{ct,eff}}{2,9} \right) \frac{h}{10 \left(h - d \right)}$$
[7.122]

where:

ϕ_s is the adjusted maximum bar diameter

ϕ_s^* is the maximum bar diameter obtained from Figure 7.103N

h is the overall thickness of the member

d is the depth to the centroid of the outer layer of reinforcement from the opposite face of the concrete (see Figure 7.1(c) in Part 1).

$f_{ct,eff}$ is the effective mean value of the tensile strength of the concrete as defined in Part 1 where $f_{ct,eff}$ is in MPa.

For cracking caused dominantly by restraint, the bar sizes given in Figure 7.103N should not be exceeded where the steel stress is the value obtained immediately after cracking (ie. σ_s in Expression 7.1)

For cracks caused dominantly by loading, either the maximum bar sizes from Figure 7.103N or the maximum bar spacings from Figure 7.104N may be complied with. The steel stress should be calculated on the basis of a cracked section under the relevant combination of actions.

For intermediate values of design crack width, values may be interpolated.

7.3.4   Calculation of crack width

Addition after Application Rule (5)

(106)   Information on the calculation of crack widths in members subjected to restrained thermal or shrinkage strains is given in Informative Annexes L and M.

Key
X   reinforcement stress, σ_s (N/mm²)
Y   maximum bar diameter (mm)

Figure 7.103N — Maximum bar diameters for crack control in members subjected to axial tension

Key
X   reinforcement stress, σ_s (N/mm²)
Y   maximum bar spacing (mm)

Figure 7.104N — maximum bar spacings for crack control in members subjected to axial tension

Addition after 7.3.4

7.3.5   Minimising cracking due to restrained imposed deformations

(101)   Where it is desirable to minimise the formation of cracks due to restrained imposed deformations resulting from temperature change or shrinkage, this may be achieved for Class 1 structures (see Table 7.105) by ensuring that the resulting tensile stresses do not exceed the available tensile strength $f_{ctk,0.05}$ of the concrete, adjusted, if appropriate, for the two-dimensional state of stress (see Annex QQ of EN 1992-2) and, for Class 2 or Class 3 structures where a liner is not used, by ensuring that the whole section remains in compression. This may be achieved by:

— limiting the temperature rise due to hydration of the cement.

— removing or reducing restraints.

— reducing the shrinkage of the concrete

— using concrete with a low coefficient of thermal expansion

— using concrete with a high tensile strain capacity (Class 1 structures only)

— application of prestressing

(102)   It will generally be sufficiently accurate to calculate the stresses assuming the concrete to be elastic and to allow for the effects of creep by use of an effective modulus of elasticity for the concrete. Informative Annex L provides a simplified method of assessing stresses and strains in restrained concrete members which may be used in the absence of more rigorous calculation.

Section 8   Detailing provisions

8.10.1 Prestressing units

8.10.3 Horizontal and vertical spacing

8.10.3.3   Post-tensioning

Addition after Application Rule (1)

(102) In the case of circular tanks with internal prestressing, care needs to be taken to avoid the possibility of local failures due to the tendons breaking out through the inside cover. In general, this will be avoided if the theoretical centroid of the horizontal cables lies in the outer third of the wall. Where the cover provisions make this impossible, this requirement may be relaxed provided the tendon duct remains within the outer half of the wall.

(103)   The diameter of a duct within a wall should generally not exceed κ times the wall thickness.

NOTE   The value of κ for use in a country may be found in its National Annex. The recommended value is $\kappa = 0,25$.

(104)   The prestressing force on a wall should be distributed as evenly as possible. Anchorages or buttresses should be so arranged as to reduce the possibilities of uneven force distribution unless specific measures are taken to take the effects into account.

(105)   Where structures subjected to elevated temperatures containing vertical unbonded tendons are used, it has been found that the protective grease is liable to run out. To avoid this, it is better to avoid the use of unbonded prestressing tendons as vertical prestress. If they are used, means should be provided to enable the presence of protective grease to be checked and renewed if necessary.

8.10.4 Anchorages and couplers for prestressing tendons

Addition after Application Rule (5)

(106)   If anchorages are located on the inside of tanks, particular care should be taken to protect them against possible corrosion.

Section 9 Detailing of members and particular rules

9.6   Reinforced concrete walls

Addition after 9.6.4

9.6.5   Corner connections between walls

(101)   Where walls are connected monolithically at a corner and are subjected to moments and shears which tend to open the corner (i.e. the inner faces of the walls are in tension), care is required in detailing the reinforcement to ensure that the diagonal tension forces are adequately catered for. A strut and tie system as covered in 5.6.4 of EN 1992-1-1 is an appropriate design approach.

9.6.6   Provision of movement joints

(101) If effective and economic means cannot otherwise be taken to limit cracking, liquid retaining structures should be provided with movement joints. The strategy to be adopted will depend on the conditions of the structure in service and the degree of risk of leakage which is acceptable. Different procedures for the satisfactory design and construction of joints have been developed in different countries. It should be noted that the satisfactory performance of joints requires that they are formed correctly. Furthermore, the sealants to joints frequently have a life considerably shorter than the design working life of the structure and therefore in such cases joints should be constructed so that they are inspectable and repairable or renewable. Further information on the provision of movement joints is given in Informative Annex N. It is also necessary to ensure that the sealant material is appropriate for the material or liquid to be retained.

9.11 Prestressed walls

9.11.1 Minimum area of passive reinforcement and cross-sectional dimensions

(101)   Where there is no vertical prestressing (or no inclined prestressing in inclined walls), vertical (or inclined) reinforcement should be provided on the basis of reinforced concrete design.

(102)   The thickness of walls forming the sides of reservoirs or tanks should generally not be less than t_1 mm for class 0 or t_2 mm for classes 1 or 2. Slipformed walls should not be thinner than t_2 mm whatever the class and the holes left by the lifting rods should be filled with a suitable grout.

NOTE   The values of t_1 and t_2 for use in a country may be found in its National Annex. The recommended value for t_1 is 120 mm and for t_2 is 150 mm.

Annex K
(informative)

Effect of temperature on the properties of concrete

K.1 General

(101)   This Annex covers the effects on the material properties of concrete of temperatures in the range -25 °C to +200 °C. Properties covered are: strength and stiffness, creep and transitional thermal strain.

(102)   In all cases the changes in properties are strongly dependant on the particular type of concrete used and the Annex should not be considered to provide more than general guidance.

K.2 Material properties at sub-zero temperatures

(101)   When concrete is cooled to below zero, its strength and stiffness increase. This increase depends mainly on the moisture content of the concrete: the higher the moisture content, the greater is the increase in strength and stiffness. It should be noted that the enhancement in properties would apply only to structures, which would be permanently below - 25° C.

(102)   Cooling concrete to –25 °C leads to increases in the compressive strength of:

— around 5 N/mm^2 for partially dry concrete

— around 30 N/mm^2 for saturated concrete.

(103)   The expressions given in 3.1.2.4(4) for tensile strength may be modified to give the effect of temperature as follows:

$$f_{ctx} = \alpha f_{ckT}^{2/3} \qquad\qquad [K.1]$$

where:

f_{ctx} = tensile strength, however defined (see Table K.1).

α = a coefficient taking account of the moisture content of the concrete. Values of α are given in Table A.1.

f_{ckT} = the characteristic compressive strength of the concrete modified to take account of temperature according to (102) above.

Table K.1 — Values of α for saturated and dry concrete

Definition of tensile strength (f_{ctx})	Saturated concrete	air dry concrete
f_{ctm}	1,56	0,30
$f_{ctk\ 0,05}$	1,30	0,21
$f_{ctk\ 0,95}$	2,43	0,39

(104)   Cooling concrete to –25 °C leads to increases in the modulus of elasticity of:

—   around 2 000 N/mm^2 for partially dry concrete

—   around 8 000 N/mm^2 for saturated concrete.

(105)   Creep at sub-zero temperatures may be taken to be 60 % to 80 % of the creep at normal temperatures. Below –20 °C creep may be assumed to be negligible.

K.3 Material properties at elevated temperatures

(101)   Information on the compressive strength and tensile strength of concrete at temperatures above normal may be obtained from 3.2.2 of EN 1992-1-2.

(102)   The modulus of elasticity of concrete may be assumed to be unaffected by temperature up to 50 °C. For higher temperatures, a linear reduction in modulus of elasticity may be assumed up to a reduction of 20 % at a temperature of 200 °C.

(103)   For concrete heated prior to loading, the creep coefficient may be assumed to increase with increase in temperature above normal (assumed as 20 °C) by the appropriate factor from Table K.2

Table K.2 — Creep coefficient multipliers to take account of temperature where the concrete is heated prior to loading

Temperature (°C)	Creep coefficient multiplier
20	1,00
50	1,35
100	1,96
150	2,58
200	3,20
NOTE The values in the table have been deduced from CEB Bulletin 208 and are in good agreement with multipliers calculated on the basis of an activation energy for creep of 8 kJ/mol.	

(105)   In cases where the load is present during the heating of the concrete, deformations will occur in excess of those calculated using the creep coefficient multipliers given in (4) above. This excess deformation, the transitional thermal strain, is an irrecoverable, time-independent strain which occurs in concrete heated while in a stressed condition. The maximum transitional thermal strain may be calculated approximately from the expression:

$$\varepsilon_{Tr} = k\sigma_c\varepsilon_{Th}/f_{cm} \qquad\qquad\qquad [K.2]$$

where:

   κ = a constant obtained from tests. The value of κ will be within the range $18 \leq \kappa \leq 2,35$

   f_{cm} = the mean compressive strength of the concrete

   ε_{Tr} = the transitional thermal strain

   ε_{Th} = the free thermal strain in the concrete (= temperature change $\times$ the coefficient of expansion)

   σ_c = the applied compressive stress

Annex L
(informative)

Calculation of strains and stresses in concrete sections subjected to restrained imposed deformations

L.1 Expressions for the calculation of stress and strain in an uncracked section

(101)   The strain at any level in a section is given by:

$$\varepsilon_{az} = (1 - R_{ax})\, \varepsilon_{i_{av}} + (1 - R_m)(1/r)(z - \underline{z}) \qquad [L.1]$$

and the stress in the concrete may be calculated from:

$$\sigma_z = E_{c,eff}(\varepsilon_{iz} - \varepsilon_{az}) \qquad [L.2]$$

where

R_{ax} = factor defining the degree of external axial restraint provided by elements attached to the element considered

R_m = factor defining the degree of moment restraint provided by elements attached to the element considered. In most common cases R_m may be taken as 1,0

$E_{c,eff}$ = effective modulus of elasticity of the concrete allowing for creep as appropriate.

$\varepsilon_{i_{av}}$ = average imposed strain in the element (i.e. the average strain which would occur if the member was completely unrestrained)

ε_{iz} = imposed strain at level z

ε_{az} = actual strain at level z

z = height to section z

$\underline{z}$ = height to section centroid

$1/r$ = curvature

L.2 Assessment of restraint

(101)   The restraint factors may be calculated from a knowledge of the stiffnesses of the element considered and the members attached to it. Alternatively, practical axial restraint factors for common situations may be taken from Figure L.1 and Table L.1. In many cases (e.g. a wall cast onto a heavy pre-existing base) it will be clear that no significant curvature could occur and a moment restraint factor of 1,0 will be appropriate.

(a) Wall on base

(b) Horizontal slab between rigid restraints

(c) Sequential bay wall construction (with construction joints)

(d) Alternate bay wall construction (with construction joints)

NOTE   Values of R used in the design should be related to the practical distribution of reinforcement

Key

1   Vertical restraint factors
2   Horizontal restraint factor (obtain from table A.3 for this central zone)
3   Expansion or free contraction joints
4   (whichever is the greater)
5   Potential primary cracks

Figure L.1 — Restraint factors for typical situations

Table L.1 — Restraint factors for central zone of walls shown in Figure M.1(a)

Ratio L/H (see Fig A.3.1)	Restraint factor at base	Restraint factor at top
1	0,5	0
2	0,5	0
3	0,5	0,05
4	0,5	0,3
>8	0,5	0,5

Annex M
(informative)

Calculation of crack widths due to restraint of imposed deformations

M.1 General

The forms of imposed deformation covered in this Appendix are shrinkage and early thermal movements due to cooling of members during the days immediately after casting.

There are two basic practical problems which need to be addressed. These relate to different forms of restraint and are as sketched below.

(a) restraint of a member at its ends   (b) restraint along one edge

Figure M.1 — Types of restraint to walls

The factors controlling the cracking in these two cases are rather different; and both are of real practical significance. (a) occurs when a new section of concrete is cast between two pre-existing sections. (b) is particularly common and arises where a wall is cast onto a pre-existing stiff base. (a) has been researched extensively over the past few decades years and is reasonably well understood. (b) has not been studied so systematically and there appears to be little published guidance.

M.2 Restraint of a member

(a) Restraint of member at its end

The maximum crack width may be calculated using Expression 7.8 in EN 1992-1-1 where (ε_{sm} - ε_{cm}) is calculated from expression M.1

$$(\varepsilon_{sm} - \varepsilon_{cm}) = 0{,}5\alpha_e \, k_c k f_{ct,eff} \, (1 + 1/(\alpha_e \rho))/E_s \qquad [\text{M.1}]$$

For checking cracking without direct calculation, σ_s may be calculated from Expression M.2 which may then be used with Figures 7.103N and 7.104N to obtain a suitable arrangement of reinforcement.

$$\sigma_s = k_c k f_{ct,eff}/\rho \qquad [\text{M.2}]$$

where ρ is A_s/A_{ct} and A_{ct} is the area of concrete in tension as defined in 7.3.2.

(b) A long wall restrained along one edge

Unlike the end restrained situation, the formation of a crack in this case only influences the distribution of stresses locally and the crack width is a function of the restrained strain rather than the tensile strain capacity

of the concrete. A reasonable estimate of the crack width can be made by taking the value of ($\varepsilon_{sm} - \varepsilon_{cm}$) given by expression M.3 in expression 7.8 in EN 1992-1-1.
$$(\varepsilon_{sm} - \varepsilon_{cm}) = R_{ax}\varepsilon_{free} \qquad\qquad [M.3]$$

where

R_{ax} = the restraint factor. This is considered in Informative Annex L.

ε_{free} = the strain which would occur if the member was completely unrestrained.

Figure M.2 illustrates the difference between the cracking in the two restraint situations.

Figure M.2 — relation between crack width and imposed strain for edge and end restrained walls

Annex N
(informative)

Provision of movement joints

(101)   There are two main options available:

a)   design for full restraint. In this case, no movement joints are provided and the crack widths and spacings are controlled by the provision of appropriate reinforcement according to the provisions of 7.3.

b)   design for free movement. Cracking is controlled by the proximity of joints. A moderate amount of reinforcement is provided sufficient to transmit any movements to the adjacent joint. Significant cracking between the joints should not occur. Where restraint is provided by concrete below the member considered, a sliding joint may be used to remove or reduce the restraint.

Table N.1 indicates the recommendations for the options.

Table N.1 — Design of joints for the control of cracking

Option	Method of control	Movement joint spacing	Reinforcement
(a)	continuous – full restraint	Generally no joints, though some widely spaced joints may be desirable where a substantial imposed deformation (temperature or shrinkage) is expected.	Reinforcement in accordance with Chapters 6 and 7.3
(b)	Close movement joints – minimum restraint	Complete joints at greater of 5 m or 1.5 times wall height	Reinforcement in accordance with Chapter 6 but not less than minimum given in 9.6.2 to 9.6.4.
